THE OBSERVATION AND ANALYSIS OF STELLAR PHOTOSPHERES

Most of what we know about stars is learned from studying the light from their photospheres. *The Observation and Analysis of Stellar Photospheres* describes the equipment, observational techniques, and analysis used in the investigation of stellar photospheres. This third edition builds on the success of the previous editions, improving the presentation, and revising topics and results to keep up-to-date with the latest research. Exercises have been added for each chapter.

The first half of the book develops the tools of analysis and the second half demonstrates how they can be applied. Topics covered include radiation transfer, models of stellar photospheres, spectroscopic equipment, how to observe stellar spectra, and techniques for measuring stellar temperatures, radii, surface gravities, chemical composition, velocity fields, and rotation rates. Up-to-date results for real stars are included. Useful data can be found throughout the text and in the appendices, and there are extensive references to the primary literature.

This textbook is for advanced undergraduate and graduate students studying stellar atmospheres or stellar physics. It presents introductory material from the basics and develops it to a professional level. It is ideal for use on university courses, and also includes a wealth of reference material useful to research scientists.

DAVID F. GRAY is Director of the Elginfield Observatory and Professor of Astronomy at the University of Western Ontario, London, Canada, where he has held positions since 1966. He has served on, organized and chaired advisory committees for organizations such as the International Astronomical Union, the Canadian Astronomical Society, and the Canada–France–Hawaii Telescope. He was president of Commission 36, on the Theory of Stellar Atmospheres between 1988 and 1991, and served on the observing-time allocation panel of the Hubble Space Telescope in 1996.

Professor Gray has published numerous papers in journals including *The Astrophysical Journal*, *Publications of the Astronomical Society of the Pacific*, *The Astronomical Journal*, *Nature*, and *Solar Physics*. He has written or contributed chapters to several books, and previous editions of this book have been used widely, including translations into Russian and Chinese. He has also edited three volumes of conference proceedings for the IAU. He is a member of the Canadian Astronomical Society, the International Astronomical Union, the Astronomical Society of the Pacific, Sigma Xi Honorary Society, and the American Astronomical Society.

<i>Preface to the first edition</i>	<i>page</i> xiii
<i>Preface to the second edition</i>	xv
<i>Preface to the third edition</i>	xvi
1 Background	1
What is a stellar atmosphere?	1
Spectral types	3
Magnitudes and color indices	7
The Hertzsprung–Russell diagram	10
The gas laws	10
The velocity distributions	12
Atomic excitation and ionization in thermodynamic equilibrium	13
Stellar catalogues, tables, and atlases	18
References	20
Questions and exercises	22
2 Fourier transforms	26
The definition	26
Some common transforms	29
Data sampling and data windows	34
Convolutions	36
Convolution with a δ -function	37
Convolutions of Gaussians and dispersion profiles	38
Resolution: our blurred data	39
Sampling and aliasing	40
Useful theorems	42
Numerical calculation of transforms	43

Noise transfer between domains	45
Time-series analysis	47
<i>References</i>	50
<i>Questions and exercises</i>	50
3 Spectroscopic tools	52
Spectrographs: some general relations	52
Diffraction gratings	54
The blazed reflection grating	61
Wavelength of the true blaze	65
Shadowing	67
Grating ghosts	69
Dispersion, slit magnification, and spectral resolution	72
Echelle spectrographs	75
Multi-object spectroscopy	78
Spectra from interferometers	78
Aspects of telescopes	83
<i>References</i>	85
<i>Questions and exercises</i>	87
4 Light detectors	89
Quantum efficiency and spectral response	90
Linearity	90
Silicon-diode arrays	92
Background and cosmic rays	95
Noise in the measurements	96
Choosing a detector to maximize s/n	97
Dynamic range and well capacity	99
Measuring the noise of a detector	100
Spatial resolution	101
Photomultiplier tubes	104
The photographic plate	105
<i>References</i>	106
<i>Questions and exercises</i>	106
5 Radiation terms and definitions	107
Specific intensity	107
Flux	109
The K integral and radiation pressure	111
The absorption coefficient and optical depth	113

	<i>Contents</i>	vii
	The emission coefficient and the source function	113
	Pure isotropic scattering	114
	Pure absorption	115
	The Einstein coefficients	115
	<i>Questions and exercises</i>	117
6	The black body and its radiation	118
	Observed relations	119
	Planck's radiation law	121
	Numerical values of black-body radiation	123
	The black body as a radiation standard	124
	<i>References</i>	125
	<i>Questions and exercises</i>	125
7	Radiative and convective energy transport	127
	The transfer equation and its formal solution	127
	The transfer equation for different geometries	129
	The flux integral	133
	The mean intensity and K integrals	134
	Exponential integrals	134
	Radiative equilibrium	136
	The grey case	139
	Convective transport	141
	Conditions for convective flow	143
	The mixing-length formulation	144
	<i>References</i>	145
	<i>Questions and exercises</i>	146
8	The continuous absorption coefficient	147
	The origins of continuous absorption	147
	The stimulated emission factor	148
	Neutral hydrogen	149
	The negative hydrogen ion	154
	Other hydrogen continuous absorbers	157
	Absorption by helium	158
	Electron scattering	160
	Other sources of continuous absorption	163
	Line opacity	165
	The total absorption coefficient	166
	<i>References</i>	167
	<i>Questions and exercises</i>	169

9	The model photosphere	170
	The equation of hydrostatic equilibrium	171
	The temperature distribution in the solar photosphere	174
	Temperature distributions in other stars	178
	The $P_g - P_c - T$ relation	181
	Completion of the model	185
	The geometrical depth	185
	Computation of the spectrum	186
	Properties of models: pressure relations	189
	The effects of chemical composition	193
	Changes with effective temperature	196
	Tabulations of model photospheres	197
	Reflection	198

Preface to the first edition

The remarkable nature of stars is transmitted to us by the light they send. The light escapes from the outer layers of the star – called, by definition, the atmosphere. The complete atmosphere of a star can be viewed comprehensively as a transition from the stellar interior to the interstellar medium. And yet almost the whole visible stellar spectrum comes from a relatively thin part called the photosphere. Obviously we cannot disconnect the photosphere from the adjacent portions of the atmosphere, but in actual fact it is the only region we can study extensively for most stars. It is for this reason that the photosphere has taken its place as the central theme of this book.

Several books have appeared during the last decade dealing with the *theory* of stellar atmospheres. These works are for the most part excellent. It is to the material largely omitted by these books that the present treatise is directed. My students and I have felt for some time the need of a book that presents the basics of the field through the eyes of an observer and analyzer of stellar atmospheres.

An introduction to a subject, in my opinion, should be presented in a way that can be understood by a reader who has not studied the topic before. It follows that the material should be presented in as simple and straightforward a manner as possible. The Fourier transform (as covered in Chapter 2) is a unifying theme helping to accomplish this aim. Transforms lead naturally into the material on data collection, optical instruments, the instrumental profile, line absorption coefficients, velocity fields, and spectral line analysis. In addition, I have selected and developed topics that I consider to be important to those of us who look at stars and attempt to understand what we see. At the same time, I have tried to present the material in the least complicated manner. The word “complicated” is affixed to things that are difficult to understand. Complicated things consequently are often unsuitable topics for the novice. We should seek not the most general case conceivable, but the least complicated case that is serviceable (a version of the principle of minimum assumption).

The development of each of the main topics starts at an elementary level, proceeds with a discussion of the topic, and ends by pointing the direction to the more advanced literature. It should be easy to expand from this book into the areas holding an attraction for you. Realizing that astrophysics is a very dynamic field, I have documented (or otherwise made clear) the source of the material used in examples. When no source is indicated, the material is from observations or calculations of my own. The references in general have been selected because they are good illustrations of the material being discussed or because they have a basic lasting approach to the subject. I have also biased the referencing toward good starting points in the literature and toward review articles and journals to which the student is likely to have access. The references are listed at the end of each chapter and ordered according to the author's name and date of publication.

The first two chapters contain preparatory material. The main theme starts in Chapter 3 with a discussion of spectroscopic tools. Generally the continuous spectrum topics are developed first, followed by the somewhat more involved subject of the line spectrum. From Chapter 14 (Chemical analysis) through to Chapter 18, the material is oriented completely toward analysis and deduction. These later chapters are closely interlinked with the preceding chapters.

The book is suitable as a text for a one-year course and as a reference to the more advanced reader.

Preface to the second edition

Wonderful growth has occurred in our understanding of stellar photospheres during the 15 years since the appearance of the first edition of “Photospheres.” I have managed to retain the same chapter names and the general plan of the first edition, and many of the equation numbers are also the same. But a significant portion of the material is new or revised. A revolution in light detectors has given us hundreds of times greater efficiency in measuring stellar spectra; Chapter 4 on detectors has been re-done. The astronomical literature is burgeoning with new results on the structure of photospheres, chemical abundances, radius measurements, stellar rotation, and photospheric velocity fields. Many of these results have been incorporated in this second edition, of course. At the same time, I stayed with my original purpose of making this volume an introduction to the subject. Unhappily, this means leaving out numerous exciting topics. My book *Lectures* (Gray 1988) takes up some of these, and it is recommended as a second installment, after the material in “Photospheres” has been mastered.

More than ever, the reader should keep in mind the fundamental nature of the stellar photosphere: of interest in its own right, with marvelous and intriguing physics, yet the link between the interior and chromospheres, coronae, and interstellar surroundings, and the source of most of our basic information about stars and stellar systems.

Once again, I thank my students and colleagues for their help and patience.

Preface to the third edition

Studies of stars continue to flourish. More detailed and sophisticated observations continue to be made, analysis tools are honed, understanding grows for more complex situations. The beauty of the stars is integrated more fully into our lives. I hope you enjoy the many revisions incorporated in this third edition of *Photospheres*: new figures, more complete data sets, re-organization of some of the material, a cleaner presentation of several topics, and some exercises and questions to help you probe the material.

I extend my thanks to J. Power for proofreading and to the many others who have guided my thoughts, given me corrections and suggestions, and contributed their efforts to knowing the stars.
