THE CIRCUITRY OF THE
HUMAN SPINAL CORD: SPINAL
AND CORTICOSPINAL
MECHANISMS OF MOVEMENT

Studies of human movement have proliferated in recent years. This greatly expanded and thoroughly updated reference surveys the literature on the corticospinal control of spinal cord circuits in human subjects, showing how different circuits can be studied, their role in normal movement and how they malfunction in disease states. Chapters are highly illustrated and consistently organised, reviewing, for each pathway, the experimental background, methodology, organisation and control, role during motor tasks and changes in patients with central nervous system lesions. Each chapter concludes with a helpful résumé that can be used independently of the main text to provide practical guidance for clinical studies. The final four chapters bring together the changes in transmission in spinal and corticospinal pathways during movement and how they contribute to the desired movement. This book is essential reading for research workers and clinicians involved in the study, treatment and rehabilitation of movement disorders.

Emmanuel Pierrot-Deseilligny is Emeritus Professor of Clinical Neurophysiology and Rehabilitation at the Université Pierre et Marie Curie, Paris.

David Burke is the Bushell Professor of Neurology at Royal Prince Alfred Hospital and Associate Dean (Research), Sydney Medical School, The University of Sydney.

1 General Methodology
   H Reflex and Tendon Jerk 1
     Basic Methodology (H reflex) 4
     H and M Recruitment Curve 7
     Tendon Jerk 8
     Random Alternation of Control and Conditioned Reflexes 8
     Time Resolution of the Method 8
     Recovery Cycle of the H Reflex 9
     Threshold Tracking of the H Reflex 11
     Mechanisms Acting on the Afferent Volley 11
       Alterations in the Excitability of Ia Afferents 11
       Presynaptic Inhibition of Ia Terminals 11
       Homosynaptic Depression 12
       Curtailment of the Compound EPSP by a Disynaptic Ib IPSP 12
       ‘Pool Problems’ 15
       Non-linearity in the Input–Output Relation 15
       Changes in the Recruitment Gain of the Motoneurone Pool 16
     Plateau Potentials and Amplification of Synaptic Input 17
     Quantitative Data 20
     Clinical Value 21
     The F wave 21
     Modulation of the On-Going EMG Activity 24
     Underlying Principles and Methodology 24
     Discrepant Changes in the On-Going EMG and in the H Reflex 26
     Advantages, Limitations and Conclusions 27
   Investigations on Single Motor Units 28
3 Fusimotor Mechanisms, Muscle Spindles and Their Role in the Control of Movement

Background 110
Methodology 114
Comparisons of Tendon Jerk and H Reflex 114
Nerve Blocks 115
Microneurography 115
Exploiting the Thixotropic Properties of Intrafusal Fibres 117
Critique of the Tests to Study Fusimotor Drive 117
Organisation and Pattern of Connections 118
Background Drive to Relaxed Muscles 118
Discharge Rates 118
Effect of Muscle Vibration on Human Spindles 119
Reflex Activation of Fusimotor Neurones 121
Supraspinal Activation of Fusimotor Neurones 123
Motor Tasks and Physiological Implications 123
Remote Muscle Contraction 123
Motor Preparation and Imagery 124
Deliberate Voluntary Effort 125
Isometric (Restraint) Contractions 125
Concentric and Eccentric Contractions 127
Activation of γ and β Motoneurones 127
Natural Unrestrained Movements 127
Possible Role of the Fusimotor System during Movement 128
Studies in Patients and Clinical Implications 129

Acknowledgements

This book is dedicated to the memory of Anders Lundberg, whose work and personal support have provided the inspiration behind most of the research described here.

Writing this book would not have been possible without the understanding, life-long support and benign tolerance that we have received throughout our careers from Evelyne and Katre, who have allowed us to pursue our interests even when the demands placed on them were unreasonable and who have, in recent year, put much on hold while we completed this work.

Geneviève Bard and Mary Sweet have provided us with invaluable assistance in collating references and getting the text into presentable order. We are grateful for the friendship, loyalty and meticulous attention to detail that has characterised their association with us over more than two decades.

The studies reported here represent the intellectual achievements of collaborators, colleagues and students. We are grateful to everyone whose work is reported here, and to our colleagues and collaborators and their publishers who have allowed us to reproduce figures from their original work.

Finally, we are indebted to L’Institut National de la Santé et de la Recherche Médicale (INSERM) and the National Health & Medical Research Council of Australia (NHMRC) for recognising the value of research into human motor control and its disorders.
Preface

This book is the direct descendant of our book entitled *The Circuitry of the Human Spinal Cord: Its Role in Motor Control and Movement Disorders*, published in 2005 by Cambridge University Press. A revised and updated edition was needed because in 7 years new and more recent data have changed views about the role of the spinal cord in the control of limb movement. This revised edition also takes into account the development and rapid uptake of investigations using transcranial stimulation of the motor cortex. Thus, much more attention has been put on the corticospinal control of movement and transcortical pathways. Neural plasticity, whether underlying learning a new skill by healthy subjects or compensatory mechanisms for the neural changes associated with ageing or disease, has also been the subject of many recent investigations that deserve to be considered.

The book is dedicated to Anders Lundberg (1920–2009). Anders Lundberg is rightfully seen as the father of modern spinal cord neurophysiology, on how spinal circuitry is mobilised by descending commands and how feedback modifies the command at spinal cord level. Anders Lundberg was an outstanding leader, an intense and focused researcher, a tough critic, a good listener and inspiring mentor. He and his students provided much of the background data from animal experiments for the human studies which this book attempts to summarise. Above all, not only did he lead the world in the definition of interneuronal mechanisms in the spinal cord but he also developed hypotheses about how these mechanisms would be used in the intact organism. In later years, having defined the C3–C4 propriospinal system in the cat, he undertook behavioural experiments to confirm its role...
in movement, and it remains the only carefully documented interneuronal system for which a functional purpose has been clearly identified. His enthusiasm and enormous intellect have provided an impetus for us to show how discoveries from animal experiments have benefited the human condition, despite the adaptations that are necessary to cater for the greater motor repertoire of human subjects.

In the preface to our previous book, we wrote: Over recent years, reappraisal of the role of direct cortico-motoneuronal projections in higher primates including humans has led to the view that the control of movement resides in the motor cortical centres that drive spinal motoneurone pools to produce the supraspinally crafted movement. This view belies the complex interneuronal machinery that resides in the spinal cord. It is a thesis of this book that the final movement is only that part of the supraspinally derived programme that the spinal cord circuitry deems appropriate. This statement remains, we believe, as true today as it was in 2005 and it is also a driving motivation behind this volume. As research interest shifts to the complexities of the cortical mechanisms in the control of movement, so too has the thrust of this new book shifted to encompass transcortical reflexes, motor cortex excitability and corticospinal mechanisms in greater detail. Nevertheless, it is timely to remind the reader that limb movements can be planned and their programs initiated by the brain but they cannot be performed without a spinal cord and they cannot be performed gracefully without the intricate feedback systems that reside within it.

As mentioned above, there has been an explosion of literature on motor control over the past 7 years, much of it devoted to cortical mechanisms preceding and associated with movement, and even some that do not have any direct influence on spinal circuitry. However, even in the latter instance, the state of the spinal cord is important when the procedures involved in testing the cortical circuitry depend on the modulation of a response that is transmitted through spinal mechanisms. In reviewing the literature for this book, we have become concerned that so simple a fact has been so often ignored in publications, even in prestigious journals.

However, the justification for a new book ultimately resides not in restating the obvious but in whether there is anything new to say, and accordingly it should be asked, precisely what is new in this book?

- To understand the influence of cortical mechanisms on the spinal motoneurone pools it is necessary to understand, first, how segmental mechanisms can modulate the command signal and, second, the limitations of techniques that can be used in human subjects to demonstrate appropriate changes. Accordingly, the structure of the initial chapters in this new book recapitulates that of the previous book – but each has been updated to cover new findings, new techniques and new appreciations of advantages and disadvantages.

- In a new chapter, the largest in this volume, we focus more fully on the techniques (and their limitations) used to study cortical and corticospinal mechanisms in the control of movement and on the results of such studies. It thereby provides an overview that integrates spinal and cortical mechanisms so that those who work at one end of the neuraxis can appreciate the importance of the other.

- A further major advance over the last decade has been on the plastic changes in connectivity that occur with development, senescence, motor learning, disease and recovery from it. An understanding of how the nervous system can adapt to changed circumstances is the key to understanding, on the one hand, acquired differences in motor skill and, on the other hand, the compensations, sometimes dysfunctional, that occur when the nervous system is damaged. Accordingly appropriate data are highlighted in chapters focussed on specific circuits, and there is a new chapter that specifically addresses the short- and long-standing adaptations of the function of spinal and corticospinal circuits to altered demands and pathology.

**Organisation of Individual Chapters**

We have retained the same format as for the previous book, with consideration first of the different spinal pathways for which there are reliable and non-invasive
methods of investigation. Accordingly, after an extensive chapter on Methodology, we consider spinal circuitry in Chapters 2–10 with, for each circuit:

1. A brief background from animal experiments. Human investigations are indirect and it is crucial to know the essential characteristics of each pathway described in animal experiments with recordings from motoneurones and/or interneurones. Caution should always be taken in extrapolating from data obtained in ‘reduced preparations’ (anaesthetised, decerebrate or spinalised animals) to awake intact human subjects, but the validation of a technique for exploring a given pathway may require controls only possible in animal experiments, and the results in human subjects are more credible when there is a close analogy with animal experiments.

2. A critical description of the available method(s) that have been used to explore the relevant pathways selectively. For those who wish to know how methods and concepts have evolved over the years and why some interpretations were erroneous even if, at the time, influential, the methods are described in detail, with their limits and caveats, and the results obtained and their interpretation(s) are critically evaluated in each chapter. Because human studies are fraught with technical difficulties, much space has been allotted to methods and potential pitfalls.

3. The organisation and descending control (in particular corticospinal) of these pathways in human subjects. The basic organisation of each pathway may well be the same in humans and cats, but the strength of the projections of individual spinal pathways on different motoneurone pools and their descending control have been the subject of phylogenetic adaptations to different motor repertoires. For the human lower limb, more elaborate reflex assistance is required for bipedal stance and gait. That there has been this phylogenetic adaptation argues that spinal pathways have a functional role in human subjects and are not evolutionary relics.

4. The changes in transmission in these pathways during various motor tasks. How spinal reflex pathways are used in motor control cannot be deduced from experiments on ‘reduced’ animal preparations. It requires experiments performed during natural movements, as can be done in humans. This has been one major contribution of human studies to the understanding of motor control physiology. Thus, even though many of the conclusions are speculative, this book gives a large place to the probable functional implications of the described changes in transmission in spinal pathways during movement.

5. Changes in transmission in these pathways in patients with various lesions of the CNS. This has provided new insights about the pathophysiology of the movement disorder in these patients.

Overall Organisation of the Book

We have again adopted much the same organisation as previously.

**Methodology.** The general methodologies which are used for investigating pathways are considered in a first chapter with the advantages and disadvantages of each technique. There is a risk that starting with a technical chapter would dissuade the non-specialist reader from delving further into the book. However, this initial chapter is useful to understand the rationale, advantages and limitations of the different techniques used to investigate different pathways, and we consider it important for those who have no experience with a particular technique but wish to use it in human subjects. Nevertheless it is not essential for the comprehension of subsequent chapters.

**Résumés.** For those who want to get to the gist of the matter reasonably quickly each chapter terminates with a résumé of its salient points. The résumés can be used on their own without reference to the detailed text. They give a practical ‘recipe’ on the choice of the appropriate technique and its proper use in routine clinical studies, together with data on the possible functional role of the particular pathway in motor control and in the pathophysiology of movement disorders.

**Overviews.** The final four chapters summarise and synthesise the changes in transmission in spinal and corticospinal pathways during movement, and how these changes contribute to motor control, and spinal
mechanisms underlying spasticity and motor impairment in patients with Parkinson’s disease and dystonia. The physiological and pathophysiological roles of spinal and corticospinal pathways are presented using a different approach to that in the previous chapters. With respect to the previous book, these overviews have been greatly developed.

A long chapter (Chapter 11) is focused on purposeful movements and involves:

(i) an overview of the contribution made by the different spinal pathways in various kinds of movement,

(ii) an attempt to unravel the relationships between volitional control, afferent feedback (in particular through transcortical reflexes), and possible efference copy,

(iii) a description of the changes in motor cortex excitability and short interval intracortical inhibition (SICI) during the different phases of various movement, and

(iv) the role of spinal and supraspinal factors in muscle fatigue.

Chapter 12 considers the contribution of spinal and transcortical pathways in unperturbed and perturbed stance and gait.

Plastic changes in spinal and corticospinal circuits are considered in Chapter 13.

In a brief summary, Chapter 14 collates data in preceding chapters on spinal mechanisms underlying spasticity and the motor impairment in patients with Parkinson’s disease and dystonia.
Abbreviations

Ach     acetylcholine
ACT     afferent conduction time
ADM     abductor digiti minimi
AG1     first agonist burst
AG2     second agonist burst
AHP     afterhyperpolarisation
ALS     amyotrophic lateral sclerosis
ANT     antagonist burst
APB     abductor pollicis brevis
APL     abductor pollicis longus
BB      biceps brachii
BF      biceps femoris
BR      brachioradialis
CMEP    cervicomedullary motor evoked potential
CNS     central nervous system
CoM     centre of mass
CPG     central pattern generator
CPN     common peroneal nerve
CS      corticospinal tract
CSP     contralateral silent period
CT      conduction time
CUSUM   cumulative sum
CV      conduction velocity
D-wave  direct wave of the corticospinal volley
DPN     deep peroneal nerve
E1      early cutaneomuscular excitation
E2      late cutaneomuscular excitation
ECR     extensor carpi radialis
ECT     efferent conduction time
ECU     extensor carpi ulnaris
ED      extensor digitorum
