Cylindrical Antennas and Arrays

Cylindrical antennas are the radiating elements in most major radio communication systems, including broadcasting networks, cellular telephone systems and radar. In this book, the authors present practical theoretical methods for determining current distributions, input admittances and impedances, and field patterns of a wide variety of cylindrical antennas and arrays, including the isolated antenna, the two-element array, the circular array, curtain arrays, Yagi and log-periodic arrays, planar arrays and three-dimensional arrays. Coverage also includes the analysis of horizontal and vertical antennas over, on and in the earth and sea, large resonant arrays of electrically short dipoles and a chapter on the theory and techniques of experimental measurement. Written by three of the leading engineers in the field, and based on world-class research carried out at Harvard over the last 40 years, *Cylindrical Antennas and Arrays* is destined to become the basic reference for practicing engineers and advanced students for many years to come.

Ronold W. P. King is Gordon McKay Professor of Applied Physics, Emeritus at Harvard University. Since joining the Harvard faculty in 1938, he has supervised the research of over 100 Ph.D. students. He is a Life Fellow of the IEEE; a Fellow of the American Physical Society; and a member of the Bavarian Academy of Sciences and the American Academy of Arts and Sciences. He holds the Distinguished Service Award from the University of Wisconsin (1973), the Centennial Medal of the IEEE (1985), the Harold Pender Award from the University of Pennsylvania (1986), the Distinguished Achievement Award of the IEEE Antennas & Propagation Society (1991), the IEEE Graduate Teaching Award (1997), and the Chen-To Tai Distinguished Educator Award from the IEEE Antennas & Propagation Society (2001).

George J. Fikioris is a lecturer at the National Technical University of Athens (NTUA) in Greece. After obtaining his Ph.D. at Harvard University in 1993 he worked for six years as an electronics engineer at the Air Force Research Laboratory, Hanscom AFB, USA before joining the NTUA in 1999.

Richard B. Mack is a consultant with his own company, Mack Consulting, specializing in electromagnetic measurement techniques.

Contents

<i>Preface</i>	<i>page</i> xiii
<i>Preface to first edition</i>	xvii

1	Introduction	1
1.1	Linear antennas	1
1.2	Maxwell’s equations and the potential functions	3
1.3	Power and the Poynting vector	5
1.4	The field of thin linear antennas: general equations	7
1.5	The field of the electrically short antenna; directivity	11
1.6	The field of antennas with sinusoidally distributed currents; radiation resistance	13
1.7	Impedance of antenna: EMF method	16
1.8	Integral equations for the current distribution	20
1.9	Direct numerical methods	23

2	An approximate analysis of the cylindrical antenna	31
2.1	The sinusoidal current	31
2.2	The equation for the current	32
2.3	Properties of integrals	33
2.4	Rearranged equation for the current	36
2.5	Reduction of integral equation to algebraic equation	36
2.6	Evaluation of coefficients	39
2.7	The approximate current and admittance	40
2.8	Numerical examples; comparison with experiment	41
2.9	The radiation field	43
2.10	An approximate two-term theory	48
2.11	The receiving antenna	50

viii	Contents	
3	The two-element array	54
3.1	The method of symmetrical components	54
3.2	Properties of integrals	57
3.3	Reduction of integral equations for phase sequences to algebraic equations	59
3.4	The phase-sequence currents and admittances	62
3.5	Currents for arbitrarily driven antennas; self- and mutual admittances and impedances	64
3.6	Currents for one driven, one parasitic antenna	66
3.7	The couplet	67
3.8	Field patterns	68
3.9	The two-term approximation	70
4	The circular array	79
4.1	Integral equations for the sequence currents	80
4.2	Sequence functions and array properties	86
4.3	Self- and mutual admittances	88
4.4	Currents and fields; arrays with one driven element	95
4.5	Matrix notation and the method of symmetrical components	103
4.6	General formulation and solution	107
5	The circuit and radiating properties of curtain arrays	112
5.1	Comparison of conventional and two-term theories	112
5.2	Two-term theory of curtain arrays	114
5.3	Example: the three-element array	124
5.4	Electronically scanned arrays	128
5.5	Examples of the general theory for large arrays	137
5.6	The special case when $\beta_0 h = \pi/2$	148
5.7	Summary	151
6	Arrays with unequal elements: parasitic and log-periodic antennas	153
6.1	Application of the two-term theory to a simple parasitic array	153
6.2	The problem of arrays with parasitic elements of unequal lengths	160
6.3	Application to the Yagi–Uda array	162

ix	Contents	
	6.4 Evaluation of coefficients for the Yagi–Uda array	167
	6.5 Arrays with half-wave elements	170
	6.6 The far field of the Yagi–Uda array; gain	173
	6.7 Simple applications of the modified theory; comparison with experiment	179
	6.8 The three-element Yagi–Uda array	182
	6.9 The four and eight director Yagi–Uda arrays	190
	6.10 Receiving arrays	198
	6.11 Driven arrays of elements that differ greatly in length	208
	6.12 The log-periodic dipole array	215
	6.13 Analysis of the log-periodic dipole array	216
	6.14 Characteristics of a typical log-periodic dipole array	222
	6.15 Frequency-independent properties of the log-periodic dipole array	228
	6.16 Experimental verification of the theory for arrays of unequal dipoles	239
7	Planar and three-dimensional arrays	241
	7.1 Vector potentials and integral equations for the currents	241
	7.2 Vector potential differences and integral equations	245
	7.3 Approximate distribution of current	247
	7.4 Evaluation of coefficients	249
	7.5 The field patterns	253
	7.6 The general two-element array	256
	7.7 A simple planar array	262
	7.8 A three-dimensional array of twenty-seven elements	272
	7.9 Electrical beam scanning	284
	7.10 Problems with practical arrays	288
8	Vertical dipoles on and over the earth or sea	290
	8.1 Introduction	290
	8.2 The complete electromagnetic field of a vertical dipole over the earth or sea with or without a coating	292
	8.3 The field in the air in the intermediate range	296
	8.4 The far field in the air	298
	8.5 Base-driven and grounded monopoles	303
	8.6 Vertical antennas on the earth for communicating with submarines in the ocean	308
	8.7 High-frequency dipoles over the earth; cellular telephone	314
	8.8 Vertical dipoles over a two-layered region	321

x	Contents	
	8.9 Propagation over the spherical earth	327
	8.10 Conclusion	341
9	Dipoles parallel to the plane boundaries of layered regions; horizontal dipole over, on, and in the earth or sea	343

Preface

Over three decades have passed since the publication, in 1968, of “Arrays of Cylindrical Dipoles” by R. W. P. King, R. B. Mack, and S. S. Sandler. The present volume is a revised and enlarged second edition of that work. The objectives of “Cylindrical Antennas and Arrays” are similar to those of “Arrays of Cylindrical Dipoles”: to present approximate but efficient theoretical methods for determining current distributions, input admittances, and field patterns of arrays of cylindrical dipoles; to use such methods to analyze particular types of arrays; to describe experimental methods for determining current distributions, input admittances, and field patterns; and to correlate and compare theoretical and experimental results.

The most fundamental quantities, and the ones most difficult to determine theoretically, are the current distributions on the array elements. Rather than postulating the current distributions, perhaps the most common treatment in the literature of the 1960s, “Arrays of Cylindrical Dipoles” sought to determine the current distributions on the array elements by solving integral equations. Today’s antenna and engineering literature is quite different from that of the 1960s: even elementary textbooks include discussions on determining current distributions from integral or similar equations.

As an example, consider the simplest configuration discussed in this book, the single, isolated cylindrical antenna of given length and radius. The integral equation treated in Chapter 2 is but one of the several integral or integro-differential equations that are encountered in the present-day literature. Although such equations were derived many years ago, the reasons for their increased popularity are the easy accessibility to high-speed computers and the availability of a large number of numerical methods. As a result of these developments, application of general-purpose numerical methods to the aforementioned equations is today much more common than in the 1960s.

Rather than discretizing the integral equations, the “two-term” and “three-term” theories developed in this book treat them by analytical means. These theories, which apply to elements that are not too long, are here presented as powerful alternatives to applying general-purpose numerical methods. Because the final two- and three-term formulas are quite simple in form, they require less running time when programmed in a computer. In addition, the analytical methods present a physical basis for understanding changes in the characteristics of the antenna as the parameters are

changed. Furthermore, applying numerical methods to the integral equations in this book presents difficulties that are often overlooked in the literature.

Chapter 1, which has been completely rewritten, has the same purpose as the first chapter of the 1968 edition: to introduce the reader to the theory of antennas and arrays presented in subsequent chapters by discussing some commonly used methods of studying a single antenna in free space. The chapter concludes with an introductory discussion of integral equations and the application of numerical methods, a subject discussed in greater depth in Chapter 13.

Chapters 2–5 develop the two- and three-term theories for the single isolated antenna, the two-element array, the circular array, and the curtain array, respectively. In Chapters 3–5, the array elements are assumed to be identical, parallel, and non-staggered. In Chapters 6 and 7, the two- and three-term theories are extended and applied to certain types of arrays that do not satisfy the aforementioned conditions. Apart from editing changes, Chapters 2–7 are the same as those in the first edition.

Chapters 8–13 have no counterparts in “Arrays of Cylindrical Dipoles”. Chapters 8 and 9 analyze vertical and horizontal dipoles and arrays over and on the surface of the conducting and dielectric earth or sea. Included are asphalt-coated earth and ice-coated water. A major new addition is long-distance propagation over the spherical surface of the sea.

In Chapter 10, arrays of identical, parallel, non-staggered elements are discussed once more, from the point of view of computer implementation of the two-term formulas. Some restrictions placed on the arrays of Chapters 3–5 are removed in this chapter, which also serves as an introduction to the study of the large circular array in Chapters 11 and 12.

In Chapters 11 and 12, a novel type of circular array is studied. The arrays under consideration differ from conventional circular arrays in that only one or two of the many array elements are excited and the entire array is tuned to spatial resonance. Both the integral equations and the two-term theory must be modified and extended to deal with the phenomena studied in this chapter. The modified theory is used to show that such arrays possess new, unusual and potentially useful resonant and directive properties. The analytical nature of the underlying theory is an important advantage for this study.

Although the two- and three-term theories are analytical in nature, they are not claimed to be mathematically rigorous. (Nonetheless, very good agreement between theory and experiment is obtained in Chapters 1–12.) Until shown otherwise [1], the lack of rigor is a necessity rather than a convenience: most of the integral equations dealt with in this book have no exact solutions, even in principle. From a theoretical point of view, then, one cannot do better than to find “reasonable solutions” that satisfy the integral equations approximately, and the aforementioned lack of rigor must be true for any method used to “solve” the integral equations. The main purpose of Chapter 13 is to discuss the consequences of this rather peculiar situation when general-purpose

numerical methods are applied to the integral equations in question. The case of an isolated antenna is discussed in detail, and extensions to arrays are pointed out. The special numerical difficulties associated with the circular arrays of the previous two chapters are also discussed here.

The concluding Chapter 14 discusses experimental methods, with emphasis on the measurement of antenna impedance. This chapter corresponds to Chapter 8 of the first edition; it has been significantly revised to discuss modern measurement techniques.

R. B. Mack wrote Chapter 14, G. Fikioris wrote Chapters 1 and 10–13; R. W. P. King wrote Chapters 8 and 9, and organized the present edition as a whole. In addition to the contributions of the several individuals named in the Preface to the first edition, the authors gratefully acknowledge the contribution of Chapter 5 by Sheldon S. Sandler. Without the extensive and very thorough work of Margaret Owens, both in preparing and correcting the new manuscripts and in editing Chapters 2–7, the present arrangement would not be possible. Finally, we thank Tai Tsun Wu for providing the initial and most fundamental ideas for the work in Chapters 11–13, and for guiding and inspiring the ensuing researches.

Preface to first edition

Studies of coupled antennas in arrays may be separated into two groups: those which postulate a single convenient distribution of current along all structurally identical elements regardless of their relative locations in the array and those which seek to determine the actual currents in the several elements. Virtually all of the early and most of the more recent analyses are in the first group in which both field patterns and impedances have been obtained for elements with assumed currents. Pioneer work in the determination of field patterns of arrays of elements with sinusoidally distributed currents was carried out for uniform arrays by Bontsch-Bruewitsch [1] in 1926, by Southworth [2] in 1930, by Sterba [3] and by Carter *et al.* [4] in 1931. Early studies of non-uniform arrays are by Schelkunoff [5] in 1943, by Dolph [6] in 1946, and by Taylor and Whinnery [7] in 1951. The self- and mutual impedances of arrays of elements with sinusoidally distributed currents were studied especially by Carter [8] in 1932, by Brown [9] in 1937, by Walkinshaw [10] in 1946, by Cox [11] in 1947, by Barzilai [12] in 1948, and by Starnecki and Fitch [13] in 1948. A thorough presentation of the basic theory of antennas with sinusoidal currents was given by Brückmann [14] in 1939. Actually, the current in any cylindrical antenna of length $2h$ and finite radius a is accurately sinusoidal only when it is driven by a continuous distribution of electromotive forces of proper amplitude and phase along its entire length. It is approximately sinusoidal in an isolated very thin antenna ($a \ll h$) driven by a single lumped generator primarily when the antenna is near resonance. When antennas are coupled in an array with each driven by a single generator or excited parasitically, it is generally assumed that (1) the phase of the current along each element is the same as at the driving point and (2) the amplitude is distributed sinusoidally. Both of these assumptions are reasonably well satisfied only for very thin antennas ($a \ll \lambda$) that are not too long ($h \leq \lambda/4$). Nevertheless, a very extensive theory of arrays has been developed based implicitly on one or both of these assumptions. Evidently it is correspondingly restricted in its generality.

The analysis of coupled antennas from the point of view of determining the actual distributions of current was studied for two antennas by Tai [15] in 1948 and extended to the N -element circular array by King [16] in 1950. A general analysis of arrays of coupled antennas has been given by King [17]. Unfortunately, the rigorous solution of the simultaneous integral equations for the distributions of current in the elements of an array of parallel elements is very complicated and no simple and practically

useful set of formulas was obtained. As a consequence, the extensive study of the electromagnetic fields of antennas and arrays in this earlier work (Chapters 5 and 6 in King [17]) was limited to arrays with currents in the elements that satisfied the assumptions of constant phase angle and sinusoidal amplitude. Similar restrictions are implicit in the fields calculated, for example, by Aharoni [18], Stratton [19], Hansen [20] and many others.

A practical method for obtaining solutions of the simultaneous integral equations for the distributions of current in the elements of a parallel array in a form that combines simplicity with quantitative accuracy was proposed by King [21] in 1959. In this analysis an approximate procedure was developed which provided simple, two-term trigonometric formulas for the currents in all of the arbitrarily driven or parasitic elements in a circular array of N elements in a manner that took full account of the effects of mutual interactions on the distributions of current. These formulas applied to elements up to one and one-quarter wavelengths long. The application of this new procedure to actual arrays and the experimental verification of the results were carried out in an extensive series of investigations by Mack [22]. The generalization of the method to curtain arrays was developed by King and Sandler [23, 24] in 1963 and 1964. The extension of the method to parasitic elements in arrays of the Yagi type was verified experimentally by Mailloux [25] in 1966. A modification of the theory and its application to the optimization of Yagi arrays by the use of a high-speed computer were devised by Morris [26] in 1965. In 1967 Cheong [27] extended the theory to unequal and unequally spaced elements. (The several researches were supported in part by Joint Services Contract Nonr 1866(32), Air Force Contract AF19(604)-4118 and National Science Foundation Grants NSF-GP-851 and GK-273.)

A further improvement in the simplified trigonometric representation of the current in an isolated antenna was introduced by King and Wu [28] in 1965 and extended to arrays in the present work.

This book begins with an introductory chapter that reviews the foundations and limitations of conventional antenna theory. It then proceeds to derive the new two- and three-term formulas for the isolated antenna in Chapter 2 and for two coupled antennas in Chapter 3. Chapter 4 provides the complete formulation of the new theory for the N -element circular array; Chapter 5 for the N -element curtain array of identical elements. The more difficult problem of treating elements of different lengths—notably in the Yagi array and the log-periodic antenna—is treated in Chapter 6. Chapter 7 is devoted to planar and three-dimensional arrays that include staggered and collinear elements. Chapter 8¹ is concerned with the broad problems of measurement—currents, impedances, field patterns and the correlation of theory with experiment. In the appendices summaries of programs are given for the computational analysis of circular, curtain, and Yagi arrays.²

¹ The original Chapter 8 corresponds to Chapter 14 of the present (2nd) edition.

² Much of this material is omitted from the appendices in the 2nd edition.

In the preparation of the manuscript, S. S. Sandler was responsible for Chapters 1 and 5, R. B. Mack for Chapters 4 and 8, and R. W. P. King for Chapters 2, 3, 6, and 7 and for the co-ordination of the several parts.

The authors are happy to acknowledge the important contributions of Drs Robert J. Mailloux, I. Larry Morris, and W.-M. Cheong whose researches form the basis of Chapter 6; and of V. W. H. Chang whose work underlies Chapter 7. They are grateful to Professor Tai Tsun Wu for many valuable suggestions and to Mrs Dilla G. Tingley for continuing painstaking assistance with the preparation of the manuscript, the graphical representation, the computations, and the programs. Mrs Barbara Sandler, Mrs Evelyn Mack, and Mr Chang also assisted with the programs, Mrs S. R. Seshadri with the preparation of the manuscript. Miss Margaret Owens contributed greatly to the accuracy of the presentation with her meticulous reading of the proofs. She also had a major share in the preparation of the index.
