CHAPTER 1

Vector Analysis

1.1 VECTOR ALGEBRA

1.1.1 Vector Operations

If you walk 4 miles due north and then 3 miles due east (Fig. 1.1), you will have gone a total of 7 miles, but you're not 7 miles from where you set out—you're only 5. We need an arithmetic to describe quantities like this, which evidently do not add in the ordinary way. The reason they don't, of course, is that displacements (straight line segments going from one point to another) have direction as well as magnitude (length), and it is essential to take both into account when you combine them. Such objects are called vectors: velocity, acceleration, force and momentum are other examples. By contrast, quantities that have magnitude but no direction are called scalars: examples include mass, charge, density, and temperature.

I shall use boldface (A, B, and so on) for vectors and ordinary type for scalars. The magnitude of a vector A is written |A| or, more simply, A. In diagrams, vectors are denoted by arrows: the length of the arrow is proportional to the magnitude of the vector, and the arrowhead indicates its direction. Minus A (−A) is a vector with the same magnitude as A but of opposite direction (Fig. 1.2). Note that vectors have magnitude and direction but not location: a displacement of 4 miles due north from Washington is represented by the same vector as a displacement 4 miles north from Baltimore (neglecting, of course, the curvature of the earth). On a diagram, therefore, you can slide the arrow around at will, as long as you don't change its length or direction.

We define four vector operations: addition and three kinds of multiplication.

![Figure 1.1](image1.png)

![Figure 1.2](image2.png)
Chapter 1  Vector Analysis

![Diagram](FIGURE 1.3)

(i) Addition of two vectors. Place the tail of \( \mathbf{B} \) at the head of \( \mathbf{A} \); the sum, \( \mathbf{A} + \mathbf{B} \), is the vector from the tail of \( \mathbf{A} \) to the head of \( \mathbf{B} \) (Fig. 1.3). (This rule generalizes the obvious procedure for combining two displacements.) Addition is commutative:

\[ \mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A}; \]

3 miles east followed by 4 miles north gets you to the same place as 4 miles north followed by 3 miles east. Addition is also associative:

\[ (\mathbf{A} + \mathbf{B}) + \mathbf{C} = \mathbf{A} + (\mathbf{B} + \mathbf{C}). \]

To subtract a vector, add its opposite (Fig. 1.4):

\[ \mathbf{A} - \mathbf{B} = \mathbf{A} + (-\mathbf{B}). \]

(ii) Multiplication by a scalar. Multiplication of a vector by a positive scalar \( a \) multiplies the magnitude but leaves the direction unchanged (Fig. 1.5). (If \( a \) is negative, the direction is reversed.) Scalar multiplication is distributive:

\[ a(\mathbf{A} + \mathbf{B}) = a\mathbf{A} + a\mathbf{B}. \]

(iii) Dot product of two vectors. The dot product of two vectors is defined by

\[ \mathbf{A} \cdot \mathbf{B} \equiv AB \cos \theta, \tag{1.1} \]

where \( \theta \) is the angle they form when placed tail-to-tail (Fig. 1.6). Note that \( \mathbf{A} \cdot \mathbf{B} \) is itself a scalar (hence the alternative name scalar product). The dot product is commutative,

\[ \mathbf{A} \cdot \mathbf{B} = \mathbf{B} \cdot \mathbf{A}, \]

and distributive,

\[ \mathbf{A} \cdot (\mathbf{B} + \mathbf{C}) = \mathbf{A} \cdot \mathbf{B} + \mathbf{A} \cdot \mathbf{C}. \tag{1.2} \]

Geometrically, \( \mathbf{A} \cdot \mathbf{B} \) is the product of \( A \) times the projection of \( \mathbf{B} \) along \( \mathbf{A} \) (or the product of \( B \) times the projection of \( \mathbf{A} \) along \( \mathbf{B} \)). If the two vectors are parallel, then \( \mathbf{A} \cdot \mathbf{B} = AB \). In particular, for any vector \( \mathbf{A} \),

\[ \mathbf{A} \cdot \mathbf{A} = A^2. \tag{1.3} \]

If \( \mathbf{A} \) and \( \mathbf{B} \) are perpendicular, then \( \mathbf{A} \cdot \mathbf{B} = 0 \).
1.1 Vector Algebra

Example 1.1. Let $C = A - B$ (Fig. 1.7), and calculate the dot product of $C$ with itself.

Solution

$$C \cdot C = (A - B) \cdot (A - B) = A \cdot A - A \cdot B - B \cdot A + B \cdot B,$$

or

$$C^2 = A^2 + B^2 - 2AB \cos \theta.$$

This is the law of cosines.

(iv) Cross product of two vectors. The cross product of two vectors is defined by

$$\mathbf{A} \times \mathbf{B} \equiv AB \sin \theta \, \mathbf{n}, \quad (1.4)$$

where $\mathbf{n}$ is a unit vector (vector of magnitude 1) pointing perpendicular to the plane of $\mathbf{A}$ and $\mathbf{B}$. (I shall use a hat (ˆ) to denote unit vectors.) Of course, there are two directions perpendicular to any plane: “in” and “out.” The ambiguity is resolved by the right-hand rule: let your fingers point in the direction of the first vector and curl around (via the smaller angle) toward the second; then your thumb indicates the direction of $\mathbf{n}$. (In Fig. 1.8, $\mathbf{A} \times \mathbf{B}$ points into the page; $\mathbf{B} \times \mathbf{A}$ points out of the page.) Note that $\mathbf{A} \times \mathbf{B}$ is itself a vector (hence the alternative name vector product). The cross product is distributive,

$$\mathbf{A} \times (\mathbf{B} + \mathbf{C}) = (\mathbf{A} \times \mathbf{B}) + (\mathbf{A} \times \mathbf{C}), \quad (1.5)$$

but not commutative. In fact,

$$(\mathbf{B} \times \mathbf{A}) = -(\mathbf{A} \times \mathbf{B}). \quad (1.6)$$
Chapter 1 Vector Analysis

Geometrically, $|A \times B|$ is the area of the parallelogram generated by $A$ and $B$ (Fig. 1.8). If two vectors are parallel, their cross product is zero. In particular,

$$A \times A = 0$$

for any vector $A$. (Here $0$ is the zero vector, with magnitude $0$.)

**Problem 1.1** Using the definitions in Eqs. 1.1 and 1.4, and appropriate diagrams, show that the dot product and cross product are distributive,

a) when the three vectors are coplanar;

b) in the general case.

**Problem 1.2** Is the cross product associative?

$$\left( A \times B \right) \times C = A \times \left( B \times C \right)$$

If so, prove it; if not, provide a counterexample (the simpler the better).

1.1.2 Vector Algebra: Component Form

In the previous section, I defined the four vector operations (addition, scalar multiplication, dot product, and cross product) in “abstract” form—that is, without reference to any particular coordinate system. In practice, it is often easier to set up Cartesian coordinates $x, y, z$ and work with vector components. Let $\hat{x}, \hat{y},$ and $\hat{z}$ be unit vectors parallel to the $x, y, z$ axes, respectively (Fig. 1.9(a)). An arbitrary vector $A$ can be expanded in terms of these basis vectors (Fig. 1.9(b)): 

![Diagram of vectors](attachment:image.png)
1.1 Vector Algebra

\[ \mathbf{A} = A_x \hat{x} + A_y \hat{y} + A_z \hat{z}. \]

The numbers \( A_x, A_y, \) and \( A_z \), are the “components” of \( \mathbf{A} \); geometrically, they are the projections of \( \mathbf{A} \) along the three coordinate axes \( (A_x = \mathbf{A} \cdot \hat{x}, A_y = \mathbf{A} \cdot \hat{y}, A_z = \mathbf{A} \cdot \hat{z}) \). We can now reformulate each of the four vector operations as a rule for manipulating components:

\[ \mathbf{A} + \mathbf{B} = (A_x \hat{x} + A_y \hat{y} + A_z \hat{z}) + (B_x \hat{x} + B_y \hat{y} + B_z \hat{z}) = (A_x + B_x) \hat{x} + (A_y + B_y) \hat{y} + (A_z + B_z) \hat{z}. \]  \hspace{1cm} (1.7)

**Rule (i):** To add vectors, add like components.

\[ a\mathbf{A} = (aA_x) \hat{x} + (aA_y) \hat{y} + (aA_z) \hat{z}. \]  \hspace{1cm} (1.8)

**Rule (ii):** To multiply by a scalar, multiply each component.

Because \( \hat{x}, \hat{y}, \) and \( \hat{z} \) are mutually perpendicular unit vectors,

\[ \hat{x} \cdot \hat{x} = \hat{y} \cdot \hat{y} = \hat{z} \cdot \hat{z} = 1; \quad \hat{x} \cdot \hat{y} = \hat{x} \cdot \hat{z} = \hat{y} \cdot \hat{z} = 0. \]  \hspace{1cm} (1.9)

Accordingly,

\[ \mathbf{A} \cdot \mathbf{B} = (A_x \hat{x} + A_y \hat{y} + A_z \hat{z}) \cdot (B_x \hat{x} + B_y \hat{y} + B_z \hat{z}) = A_x B_x + A_y B_y + A_z B_z. \]  \hspace{1cm} (1.10)

**Rule (iii):** To calculate the dot product, multiply like components, and add.

In particular,

\[ \mathbf{A} \cdot \mathbf{A} = A_x^2 + A_y^2 + A_z^2, \]

so

\[ A = \sqrt{A_x^2 + A_y^2 + A_z^2}. \]  \hspace{1cm} (1.11)

(This is, if you like, the three-dimensional generalization of the Pythagorean theorem.)

Similarly,\(^1\)

\[ \hat{x} \times \hat{x} = \hat{y} \times \hat{y} = \hat{z} \times \hat{z} = 0, \]
\[ \hat{x} \times \hat{y} = -\hat{y} \times \hat{x} = \hat{z}, \]
\[ \hat{y} \times \hat{z} = -\hat{z} \times \hat{y} = \hat{x}, \]
\[ \hat{z} \times \hat{x} = -\hat{x} \times \hat{z} = \hat{y}. \]  \hspace{1cm} (1.12)

\(^1\)These signs pertain to a right-handed coordinate system (\(x\)-axis out of the page, \(y\)-axis to the right, \(z\)-axis up, or any rotated version thereof). In a left-handed system (\(z\)-axis down), the signs would be reversed: \( \hat{x} \times \hat{y} = -\hat{z} \), and so on. We shall use right-handed systems exclusively.
Chapter 1 Vector Analysis

Therefore,
\[
\mathbf{A} \times \mathbf{B} = (A_x \hat{x} + A_y \hat{y} + A_z \hat{z}) \times (B_x \hat{x} + B_y \hat{y} + B_z \hat{z})
\]  
\[= (A_y B_z - A_z B_y) \hat{x} + (A_z B_x - A_x B_z) \hat{y} + (A_x B_y - A_y B_x) \hat{z}.
\]

This cumbersome expression can be written more neatly as a determinant:
\[
\mathbf{A} \times \mathbf{B} = \begin{vmatrix} \hat{x} & \hat{y} & \hat{z} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix}. 
\]  
\[\text{Rule (iv): To calculate the cross product, form the determinant whose first row is } \hat{x}, \hat{y}, \hat{z}, \text{ whose second row is } \mathbf{A} \text{ (in component form), and whose third row is } \mathbf{B}.
\]

Example 1.2. Find the angle between the face diagonals of a cube.

Solution

We might as well use a cube of side 1, and place it as shown in Fig. 1.10, with one corner at the origin. The face diagonals \( \mathbf{A} \) and \( \mathbf{B} \) are
\[
\mathbf{A} = 1 \hat{x} + 0 \hat{y} + 1 \hat{z}; \quad \mathbf{B} = 0 \hat{x} + 1 \hat{y} + 1 \hat{z}.
\]

So, in component form,
\[
\mathbf{A} \cdot \mathbf{B} = 1 \cdot 0 + 0 \cdot 1 + 1 \cdot 1 = 1.
\]

On the other hand, in “abstract” form,
\[
\mathbf{A} \cdot \mathbf{B} = AB \cos \theta = \sqrt{2} \sqrt{2} \cos \theta = 2 \cos \theta.
\]

Therefore,

\[
\cos \theta = 1/2, \quad \text{or} \quad \theta = 60^\circ.
\]

Of course, you can get the answer more easily by drawing in a diagonal across the top of the cube, completing the equilateral triangle. But in cases where the geometry is not so simple, this device of comparing the abstract and component forms of the dot product can be a very efficient means of finding angles.
1.1 Vector Algebra

Problem 1.3 Find the angle between the body diagonals of a cube.

Problem 1.4 Use the cross product to find the components of the unit vector \( \hat{n} \) perpendicular to the shaded plane in Fig. 1.11.

1.1.3 Triple Products

Since the cross product of two vectors is itself a vector, it can be dotted or crossed with a third vector to form a *triple* product.

(i) **Scalar triple product**: \( A \cdot (B \times C) \). Geometrically, \( |A \cdot (B \times C)| \) is the volume of the parallelepiped generated by \( A, B, \) and \( C \), since \( |B \times C| \) is the area of the base, and \( |A \cos \theta| \) is the altitude (Fig. 1.12). Evidently,

\[
A \cdot (B \times C) = B \cdot (C \times A) = C \cdot (A \times B),
\]

(1.15)

for they all correspond to the same figure. Note that “alphabetical” order is preserved—in view of Eq. 1.6, the “nonalphabetical” triple products,

\[
A \cdot (C \times B) = B \cdot (A \times C) = C \cdot (B \times A),
\]

have the opposite sign. In component form,

\[
A \cdot (B \times C) = \begin{vmatrix}
A_x & A_y & A_z \\
B_x & B_y & B_z \\
C_x & C_y & C_z
\end{vmatrix}.
\]

(1.16)

Note that the dot and cross can be interchanged:

\[
A \cdot (B \times C) = (A \times B) \cdot C
\]

(this follows immediately from Eq. 1.15); however, the placement of the parentheses is critical: \( (A \cdot B) \times C \) is a meaningless expression—you can’t make a cross product from a *scalar* and a vector.

![FIGURE 1.11](image1)

![FIGURE 1.12](image2)
(ii) Vector triple product: \( \mathbf{A} \times (\mathbf{B} \times \mathbf{C}) \). The vector triple product can be simplified by the so-called BAC-CAB rule:

\[
\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B}).
\]

(1.17)

Notice that

\[
(\mathbf{A} \times \mathbf{B}) \times \mathbf{C} = -\mathbf{C} \times (\mathbf{A} \times \mathbf{B}) = -\mathbf{A}(\mathbf{B} \cdot \mathbf{C}) + \mathbf{B}(\mathbf{A} \cdot \mathbf{C})
\]

is an entirely different vector (cross-products are not associative). All higher vector products can be similarly reduced, often by repeated application of Eq. 1.17, so it is never necessary for an expression to contain more than one cross product in any term. For instance,

\[
(\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}) - (\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C});
\]

\[
\mathbf{A} \times [\mathbf{B} \times (\mathbf{C} \times \mathbf{D})] = \mathbf{B}[\mathbf{A} \cdot (\mathbf{C} \times \mathbf{D})] - (\mathbf{A} \cdot \mathbf{B})(\mathbf{C} \times \mathbf{D}).
\]

(1.18)

Problem 1.5 Prove the BAC-CAB rule by writing out both sides in component form.

Problem 1.6 Prove that

\[
[A \times (\mathbf{B} \times \mathbf{C})] + [\mathbf{B} \times (\mathbf{C} \times \mathbf{A})] + [\mathbf{C} \times (\mathbf{A} \times \mathbf{B})] = \mathbf{0}.
\]

Under what conditions does \( \mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = (\mathbf{A} \times \mathbf{B}) \times \mathbf{C} \)?

1.1.4 Position, Displacement, and Separation Vectors

The location of a point in three dimensions can be described by listing its Cartesian coordinates \((x, y, z)\). The vector to that point from the origin (O) is called the position vector (Fig. 1.13):

\[
\mathbf{r} \equiv x\mathbf{\hat{x}} + y\mathbf{\hat{y}} + z\mathbf{\hat{z}}.
\]

(1.19)
1.1 Vector Algebra

I will reserve the letter $\mathbf{r}$ for this purpose, throughout the book. Its magnitude,

$$ r = \sqrt{x^2 + y^2 + z^2}, \quad (1.20) $$

is the distance from the origin, and

$$ \hat{\mathbf{r}} = \frac{\mathbf{r}}{r} = \frac{x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}}{\sqrt{x^2 + y^2 + z^2}} \quad (1.21) $$

is a unit vector pointing radially outward. The infinitesimal displacement vector, from $(x, y, z)$ to $(x + dx, y + dy, z + dz)$, is

$$ d\mathbf{l} = dx \hat{\mathbf{x}} + dy \hat{\mathbf{y}} + dz \hat{\mathbf{z}}. \quad (1.22) $$

(We could call this $d\mathbf{r}$, since that’s what it is, but it is useful to have a special notation for infinitesimal displacements.)

In electrodynamics, one frequently encounters problems involving two points—typically, a source point, $\mathbf{r}'$, where an electric charge is located, and a field point, $\mathbf{r}$, at which you are calculating the electric or magnetic field (Fig. 1.14). It pays to adopt right from the start some short-hand notation for the separation vector from the source point to the field point. I shall use for this purpose the script letter $\mathbf{s}$:

$$ \mathbf{s} \equiv \mathbf{r} - \mathbf{r}'. \quad (1.23) $$

Its magnitude is

$$ r = |\mathbf{r} - \mathbf{r}'|, \quad (1.24) $$

and a unit vector in the direction from $\mathbf{r}'$ to $\mathbf{r}$ is

$$ \hat{\mathbf{s}} = \frac{\mathbf{s}}{r} = \frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|}. \quad (1.25) $$

In Cartesian coordinates,

$$ \mathbf{s} = (x - x')\hat{\mathbf{x}} + (y - y')\hat{\mathbf{y}} + (z - z')\hat{\mathbf{z}}, \quad (1.26) $$

$$ r = \sqrt{(x - x')^2 + (y - y')^2 + (z - z')^2}, \quad (1.27) $$

$$ \hat{\mathbf{s}} = \frac{(x - x')\hat{\mathbf{x}} + (y - y')\hat{\mathbf{y}} + (z - z')\hat{\mathbf{z}}}{\sqrt{(x - x')^2 + (y - y')^2 + (z - z')^2}} \quad (1.28) $$

(from which you can appreciate the economy of the script-$\mathbf{s}$ notation).

---

**Problem 1.7** Find the separation vector $\mathbf{s}$ from the source point (2,7) to the field point (4,6,8). Determine its magnitude ($r$), and construct the unit vector $\hat{\mathbf{s}}$.

1.1.5 How Vectors Transform

The definition of a vector as “a quantity with a magnitude and direction” is not altogether satisfactory: What precisely does “direction” mean? This may seem a pedantic question, but we shall soon encounter a species of derivative that looks rather like a vector, and we’ll want to know for sure whether it is one.

You might be inclined to say that a vector is anything that has three components that combine properly under addition. Well, how about this: We have a barrel of fruit that contains $N_x$ pears, $N_y$ apples, and $N_z$ bananas. Is $\mathbf{N} = N_x \hat{\mathbf{x}} + N_y \hat{\mathbf{y}} + N_z \hat{\mathbf{z}}$ a vector? It has three components, and when you add another barrel with $M_x$ pears, $M_y$ apples, and $M_z$ bananas the result is $(N_x + M_x)$ pears, $(N_y + M_y)$ apples, $(N_z + M_z)$ bananas. So it does add like a vector. Yet it’s obviously not a vector, in the physicist’s sense of the word, because it doesn’t really have a direction. What exactly is wrong with it?

The answer is that $\mathbf{N}$ does not transform properly when you change coordinates. The coordinate frame we use to describe positions in space is of course entirely arbitrary, but there is a specific geometrical transformation law for converting vector components from one frame to another. Suppose, for instance, the $\bar{x}, \bar{y}, \bar{z}$ system is rotated by angle $\phi$, relative to $x, y, z$, about the common $x = \bar{x}$ axes. From Fig. 1.15,

$$A_y = A \cos \theta, \quad A_z = A \sin \theta,$$

while

$$\bar{A}_y = A \cos \bar{\theta} = A \cos(\theta - \phi) = A(\cos \theta \cos \phi + \sin \theta \sin \phi) = \cos \phi A_y + \sin \phi A_z,$$

$$\bar{A}_z = A \sin \bar{\theta} = A \sin(\theta - \phi) = A(\sin \theta \cos \phi - \cos \theta \sin \phi) = -\sin \phi A_y + \cos \phi A_z.$$
