3.1	Offence participations among youths suspected of offences in Stockholm 1991–1995 and their suspected co-offenders, by offence category	<i>page 40</i>
3.2	Youths suspected of offences in Stockholm 1991–1995 and their co-offenders by the number of six-month periods in which they appear in the data	41
3.3	Pairs of co-offenders among youths suspected of offences in Stockholm 1991–1995 and their co-offenders after the number of six-month periods in which they appear in the data	43
3.4	Proportion of participations in various offence types for isolates and co-offenders suspected of offences in Stockholm 1991–1995	45
3.5	Reoffending frequency from autumn 1991 to autumn 1995 for youths born 1975–1981 suspected of offences in Stockholm in spring 1991; by number of co-offenders in spring 1991	47
4.1	Proportion of suspected co-offenders of youths suspected of offences in Stockholm 1991–1995 who were younger than, born the same year as, and older than the actors themselves. Pairs	53
4.2	Proportion of boys and girls under 21 suspected of co-offending in Stockholm 1991–1995 together with individuals of the same or the opposite sex respectively. Pairs	54
4.3	Choices of co-offenders made by individuals under 21 in Stockholm in autumn 1995, grouped on the basis of the number of registered offences for which members of the pairs have been suspected between spring 1991 and spring 1995. Pairs	61

4.4	Comparison between pairs consisting of actors suspected of offences in Stockholm in autumn 1995. (1) Both actors with no known delinquent experience previously (spring 1991–spring 1995). (2) One actor with no known previous offences, the other suspected of four or more offences (spring 1991 to spring 1995). (3) Both actors suspected of four or more offences (spring 1991 to spring 1995)	63
6.1	Number, average age at first registered offence, proportion of females, and average number of co-offenders and offence participations of youths in secure facilities classified into one of the problem profile groups and suspected of offences in Stockholm between 1991 and 1995, and for their co-offenders, as well as the corresponding data for all youths suspected of offences in Stockholm during the same period	91
6.2	Average level of delinquency in the form of offences against the person, offences against property and drug offences (number of suspected offence participations) per individual 1991–1995 for individuals with different problem profiles and for their suspected co-offenders	94
8.1	Suspected offence participations in Stockholm 1991–1995 for individuals suspected of extreme right-wing offences in autumn 1995 and the members of their networks broken down into different offence categories	118
9.1	Choices of co-offenders and victims. Youths under 21 suspected of violent offences in Stockholm 1995, their co-offenders and victims, presented on the basis of ethnic background (Swedish or immigrant)	127
9.2	Individuals under 21 suspected of violent offences in Stockholm in 1995. Proportion of choices of co-offender from the perpetrator's own ethnic group, divided by the proportion of such choices that would have been made if the choice of co-offender was made completely at random from the group containing all the co-offenders studied, or from the whole of the population of Stockholm respectively	129
9.3	Individuals under 21 suspected of violent offences in Stockholm 1995. The proportion of choices of victim from the same ethnic group as the perpetrator, divided by the proportion of such choices as would be expected if the choices had been made completely at random from the group containing all the studied victims, or from the whole of the population of Stockholm respectively	131

9.4	Choice of co-offenders and victims for violent offences 1995. Proportion of ethnically suspect–suspect and suspect–victim pairs (using the same eight ethnic groups as earlier) after age, gender and place of residence of the suspects and their victims	134
10.1	Offences for which members of the Ången network were suspected between 1991 and 1995 according to the network data	147
A1	Age difference between youths suspected of offences in Stockholm 1991–1995 and their co-offenders. Pairs	170
A2	Proportion of co-offenders of same gender chosen by boys and girls suspected of offences in Stockholm 1991–1995.	171
A3	Correspondence between residential postcodes for youths suspected of offences in Stockholm 1991–1995 and their co-offenders, after offender’s age. Pairs.	171
A4	Correspondence in residential postcode between youths suspected of offences in Stockholm 1991–1995 and their co-offenders, after offender’s gender. Pairs.	172
A5	Choices of co-offenders. Proportion of co-offenders of the same as, younger and older than youths suspected of offences in Stockholm 1991–1995. Average age difference, and standard deviation, after offence type. Pairs	172
A6	Choices of co-offenders. Gender of youths suspected of offences in Stockholm 1991–1995 and their co-offenders. After offence type.	173
A7	Choices of co-offenders. Correspondence in residential postcodes among youths suspected of offences in Stockholm 1991–1995 and their suspected co-offenders, after offence type.	174
A8	Level of delinquent experience (offence participations) 1991–1995 after offence type for the youths in the various problem profile groups and their co-offenders, and for the study population as a whole.	175
A9	Ethnicity of co-offenders to youths suspected of violent offences in Stockholm 115, victims of these offences, and of the entire population of Stockholm.	176

## Social network analysis and criminology

### 1.1 Introduction

This study employs a network analytical approach to examine co-offending. The aim is to test whether a network perspective can provide new approaches and fresh insights into the character of juvenile crime in a metropolitan area.

The most fundamental difference between traditional social science and research which employs a network perspective is that network analysis stipulates the existence of observable relationships among the objects under study. Over the past few decades, social network analysis has become an increasingly common approach within the social sciences in general.<sup>1</sup> It is still employed only rarely in criminological studies,<sup>2</sup> however, despite the fact that clear parallels exist between a network perspective and many aspects of criminological thought.

Many of the classics of criminological literature contained formulations consistent with the use of a social network perspective long before this approach became popular within social science. Shaw and McKay (1942), for example, in their *Juvenile Delinquency and Urban Areas* state that 'delinquent boys in these areas have contact not only with other delinquents who are their contemporaries but also with older offenders, who in turn had contact with delinquents preceding them, and so on . . . This contact means that the traditions of delinquency can be and are transmitted down through successive generations of boys, in much the same way that language and other social forms are transmitted' (Shaw and McKay 1942: 174).

It is well established that juvenile crime is to a large extent a group phenomenon. Young people often commit offences with members of their peer

group (see for example Breckinridge and Abbot 1917; Shaw and McKay 1931, 1942; Sveri 1960; Short and Strodtbeck 1965; Klein and Crawford 1967; Gold 1970; Hood and Sparks 1970; Elliott, Huizinga and Ageton 1985; Sarnecki 1986; Short 1998a; Reiss and Farrington 1991).<sup>3</sup> We know too that delinquent juveniles often have friends who have themselves committed several offences.<sup>4</sup>

In an 'everyday' sense, social ties among criminally active young people are seen as a means whereby the young people in question exert an influence over one another to commit offences. Many parents express concern about the possibility that their teenagers may fall into 'bad company', for example.

In the scientific community too, the group-related characteristics of juvenile crime are often seen in causal terms. This is particularly true of learning and neutralisation theories such as those presented by Sutherland, Akers and Matza (Sutherland 1939; Matza 1964; Sutherland, Cressey and Luckenbill 1992; Akers 1998).

At the same time, we might also claim that all those theories which associate crime with a working class, or perhaps a more generally lower-class culture, or with different forms of subculture (e.g. Cohen 1955; Miller 1958; Cloward and Ohlin 1960; Ferrell and Sanders 1995) as well as the research tradition that has grown up around the American 'gang' (e.g. Thrasher 1927; Short and Strodtbeck 1965; Klein 1971, 1995), all stipulate the existence of a mechanism which both facilitates the spread of norms and values conducive to the commission of crime, and enables individuals to exert influence over one another. Even though the representatives of these traditions do not usually discuss how the process might operate in practice,<sup>5</sup> research of this kind requires an assumption about the existence of such a mechanism. Cohen, for instance, writes: 'The crucial condition for the emergence of new cultural forms is the existence, in effective interaction with one another, of a number of actors with similar problems of adjustment' (Cohen 1955: 59).

The most widespread view of the effect on crime of friendships among young people however is that having criminally active friends is *one of several factors* which increase the likelihood that an individual will commit offences.<sup>6</sup> The view expressed by Loeber and Farrington in this regard seems to be fairly typical. In summing up the most reliable predictors of serious and violent offending in youths aged between 12 and 14, they mention a 'lack of strong social ties, antisocial peers, non-serious delinquent acts, poor school attitude and performance and psychological conditions such as impulsivity' (Loeber and Farrington 1998: xxii). Associating with

antisocial peers is also mentioned as being among the strongest predictors of serious and violent offending among those aged between 6 and 11 years.

Like any other social activity then, delinquency can be explained, at least in part, with reference to the relationships an individual establishes with others. And it is just this quality that makes the network perspective so potentially useful in the analysis of crime.

The following section takes up the question of why studies focusing on relationships between delinquent juveniles may be more relevant in the context of modern society than they were in the past. Following on from this general discussion, the basic principles of social network analysis are briefly introduced, and the relevance of the network approach for a number of the classical criminological perspectives is explained.

## **1.2 Changes in the social significance of the juvenile peer group**

As has been mentioned, the central axiom of network analysis, namely that the propensity to commit criminal offences is affected by an individual's social relations, is compatible with most of the central criminological perspectives specified above. The social relations that constitute the principal focus for the current study are those existing between young delinquents and their peers. It is my contention that relations among youths and their peers are of considerably greater significance in the context of modern society than they have been before and, this being the case, it is important that such relations become the focus of serious research.

There is much to suggest that the changes witnessed by western society during this last century have increased the peer group's influence on the behaviour of young people, at the expense of the influence previously exerted by adults (Sarnecki 1997). The reasons underlying this change are to be sought in the social changes common to late industrial societies, which have led to the exclusion of young people from the labour force and the prolongation of their stay in the education system.

The introduction of compulsory education was in the first instance intended to compensate a shortfall in control which young people were experiencing at the time as a result of their new position in society (Bauman, 1992). This process then continued with the vigorous expansion of both school education (which in most western countries today lasts for at least twelve years) and other institutions such as the social services, the police, organised leisure-time activities for young people and so on. At the same time, the control over young people exerted by the family, the work environment and the neighbourhood has become less important. The type

#### 4 DELINQUENT NETWORKS: YOUTH CO-OFFENDING IN STOCKHOLM

of formal social control exercised by authorities, however, has not been able to compensate for the reduced levels of informal control which resulted from the transition to new forms of production, urbanisation and so forth.

During the 1960s and 1970s this process was on the whole regarded as a positive development, since it was seen to have freed youth from the oppression of patriarchal society. Today the negative aspects of the process are more often those that receive the attention of social commentators, not least the low level of social control to which young people are exposed, and their lack of integration into mainstream society (Sarnecki 1997).

Many criminologists (e.g.; Clarke and Cornish 1983; von Hofer 1985; von Hofer and Tham 2000) feel that during the twentieth century the economic developments witnessed by the western world have increased opportunities for crime and thus led to an increase in the crime level itself. Such changes in the criminal opportunity structure cannot by themselves explain why the delinquency of young people has increased more than that of other age groups in most western countries, however. In my opinion (Sarnecki 1997) the remarkable increase in the delinquency of young people<sup>7</sup> seen in the West is related not only to the increase in criminal opportunities but also to the way that the vertical ties linking youths and adults have been weakened, whilst the horizontal ties linking young people to their peers have become stronger. Two visible results of this process have been the reduction in the control of youth exercised by parents and the emergence of the many so called 'youth cultures' so characteristic of the second half of the twentieth century. Young people today, excluded from the labour force and lacking the firm control exercised over earlier generations by adult society, have considerably more opportunity to participate in youth cultures which are often oppositional in terms of the mainstream culture.

There is thus good reason to believe that the altered position of young people in modern society has meant that they have to some extent been able to free themselves from the control (and probably also from the oppression) of the adult establishment, and have at the same time been given much more space in which to establish and develop relations with members of their peer group. This situation is described in the following somewhat uncompromising terms by Dishion et al: '... we have become a society where many children are essentially raised by peers' (1995: 821).

This is probably one of the macro-level factors underlying the observed increase in delinquency among youths in a large part of the western world. Against this background, I believe that micro-level studies of the social ties between young people are of particular interest for criminologists.

### 1.3 Network analysis and criminological theory

#### 1.3.1 The network perspective

Since the network perspective remains relatively unknown within criminology, what follows is a short presentation of some of the concepts basic to this field of enquiry.

Stated simply, social network analysis looks at relations between social units (individuals or organisations), the patterns displayed by such relations and also at their implications (Wasserman and Faust 1994: 6). One of the most important tasks of network analysis is to attempt to explain, at least in part, the behaviour of the elements in a network by studying specific properties of the relations between these elements. Elements (in the context of this study, individuals) which are found to be close to one another (physically or socially) and which interact are generally assumed to affect one another's behaviour. It should be stressed, however, that 'face-to-face' encounters are not essential for this inter-individual influence to work, nor is it necessary that the interactions are *intended* to exert such influence (Marsden and Friedkin 1994).

Theories and empirical studies in this field appear to have developed in parallel and to some degree independently of one another in several different areas within social science. According to Borell and Johansson (1996) and Wasserman and Faust (1994) two different approaches are to be found behind the origins of the network perspective: the social-psychological and the anthropological.<sup>8</sup>

Barnes (1954) is widely held to be the first to have used the concept 'social network', but the research tradition in this area stretches back a good deal further than this. The network approach was first used in social-psychological research around the 1920s and 1930s, when the first sociograms were drawn up (Moreno 1934). Sociograms were used primarily to study relationships between individuals in a group, often a class of school children. The sociograms made it possible to see which of the pupils enjoyed the greatest popularity in a class, for example, and which of them were completely lacking in social contacts.

Sociometric techniques have also been used on occasion in the field of criminology (by among others Yablonsky 1962, Short and Strodback 1965, Klein and Crawford 1967, and Sarnecki 1986). Klein and Crawford, for example, used this method to study how often the members of a thirty-strong Los Angeles gang had contact with one another in the space of a six-month period.

With time, analyses of this type were allowed to evolve thanks to the introduction of directed graphs (Cartwright and Harary 1956). Sociometric

analyses could now differentiate among types of relation and the direction in which the relations went. Relations can thus be either reciprocal, such as when two individuals commit an offence together, or one-way, such as when one individual victimises another without provocation.

The introduction of directed graphs paved the way for the use of network analysis in epidemiological research, looking at different stages in the spread of disease. And it was soon realised that this type of scientific tool could be used to study much more than just the spread of illness. The method was also suitable for the study of the diffusion of different types of ideas and social behaviours. Coleman, Katz and Menzel (1957, 1966), for example, used this method to examine how attitudes to the use of new medicines are spread among doctors.<sup>9</sup> They found that informal networks were decisive, especially to begin with while there still existed a great deal of uncertainty as to the new medication's usefulness.

The other social-psychological approach that contributed to the development of network analysis originated during the 1930s and 1940s primarily at Harvard University, where different aspects of 'informal relations' in large systems were being studied (Scott 1991: 16). Among the research produced by this tradition, we find the classic study of the Hawthorn Western Electric Company in Chicago (Roethlisberger and Dickson 1934), which pointed to the significance of patterns of informal organisation in a workplace. For Scott, this was the first study to use the sociogram to describe 'actual relations observed in real situations' (Scott 1991: 18).

The anthropological tradition of network analysis has its origins in a group of researchers working at Manchester University during the 1950s. One of the names emerging from this tradition is Barnes (1954), referred to above, who produced the first scientific definition of the network concept in connection with his field study of a fishing community on a Norwegian island. Barnes describes the small Norwegian village in terms of the relations among the people living there. Each of the inhabitants in the village had contacts with a number of other people, who in turn had contacts with still others. One of the study's important discoveries was that the social networks found in the village had no obvious organisation and no clear leadership structure.

Another anthropologist active within this tradition was Bott (1955), who examined families in metropolitan areas and their contact networks. Bott's results showed that 'external networks' affected relationships within the family.

Mitchell (1969) was an important figure in the evolution of the anthropological network analytical tradition. Mitchell saw society as an enormous

network of interpersonal relations. He felt that research should be focused on the study of the partial networks that together make up the complete societal network. The choice of which of these partial networks to study could be based either on individuals, whose personal (ego-centred) networks could then be examined, or on networks which served special functions, such as the relations within the extended family, between business contacts, friendship ties or other similar examples. In the present study, both of these options are employed. In some instances, the personal networks of actively delinquent individuals are examined, whilst at other times the focus shifts to complete networks comprising all directly or indirectly connected co-offenders.

Mitchell also introduced a number of concepts that are now commonplace in network analytical studies, and some of these will be used here. He made a distinction between two types of network characteristic:

*morphological* characteristics, which refer to the patterning of relations in the network, such as *anchorage*, the person or persons who constitute the centre of a network, *reachability*, the extent to which an individual can be contacted by others in the network either by direct links, for example, or via mediating others, *density*, the number of links that are actually present in a network compared to the maximum possible number of links if all network members were maximally connected to one another and *range*, the number of persons to whom a certain individual is linked.

*interactional* characteristics which refer to the nature of the relations, such as the *content* of the interactions (e.g. family, friendship or co-offending), the *direction* of the interaction (one-way or reciprocal), *durability* (how long the relation lasts) *intensity* and *frequency*.

The anthropological tradition within network analysis has focused much of its attention on personal (ego-centred) networks. One study using this approach is that of Granovetter (1974) which examines the ways in which educated men from a suburb of Boston find themselves jobs. The study shows that information relating to job opportunities is gleaned not in the first instance through close relations such as those with family and close friends, but rather through the considerably weaker ties formed in the course of one's working life. Another classic study of personal networks focused on women looking to obtain an illegal abortion (Lee 1969). In this instance it was found that women found abortionists through contacts with female friends of the same age. In order to find subjects for the study, Lees used similar techniques to those employed by the women to find an abortionist.<sup>10</sup>

Over the last few decades, the use of network analysis has spread to many other areas. This diffusion has been made possible by, amongst other things, the development of statistical methods with special relevance for the treatment of network data (see for example Frank 1991; Frank and Nowicki 1993; Wasserman and Faust 1994).

One area where the network approach is widely used today is in the treatment of individuals with various kinds of social and psychological disturbances. Network therapy is now an established form of treatment employed by both social workers and psychiatrists (e.g. Svedhem (ed.) 1985, and Svedhem 1991).

The network perspective is today firmly established within sociological, anthropological and economic thought. In sociological research, for example, the concept of social mechanisms (Hedström and Swedberg 1998) builds to a large extent on such social phenomena as diffusion and other factors affecting collective behaviour. Even though criminological thought seldom takes account of group behaviour, criminological theory does contain a number of perspectives that can be said to employ a network approach to the analysis of crime. These theoretical perspectives, as mentioned above, see the causes of crime as partially or completely associated with the individual's ties to different types of social network. The following sections discuss the network analytical aspects of a number of the classic criminological theories.

### **1.3.2 Differential association**

Of the classic criminological theories, Sutherland's theory of differential association (Sutherland 1939 and 1947; Sutherland, Cressey and Luckenbill 1992) is perhaps the one that is closest to modern network analytical thought.

As we know, Sutherland is of the opinion that criminality, just like other forms of behaviour, is learned during interaction with other individuals, principally within primary groups. The learning process applies not only to the techniques necessary for the commission of offences but also to such aspects of offending as motivation, attitudes to crime, values and also to ways of rationalising what has happened. According to Sutherland, 'A person becomes delinquent because of an excess of definitions favourable to violation of law over definitions unfavourable to violation of law' (Sutherland, Cressey and Luckenbill 1992: 89). These definitions are learned primarily in the course of contacts with other individuals. In western society (Sutherland refers to the situation in America) one always has relations both to individuals who feel that legal norms should be adhered to uncondition-

ally and to individuals who feel that non-compliance with such norms is more acceptable. It is this variety of relational content that Sutherland refers to as differential association. He writes: 'Differential associations may vary in frequency, duration, priority and intensity' (Sutherland, Cressey and Luckenbill 1992: 89).

These characteristics of Sutherland's conceptualisation of differential association correspond well with the interactional characteristics ascribed to the links between network members by Mitchell (1969), who wrote that such links can vary in durability, intensity and frequency.

As I have argued, we can assume that in modern western society, it is principally the peer group, made up of friends of the same age (and slightly older), that contains models for deviant or delinquent behaviour in young people. Seen from this perspective, membership in a network of delinquent youths should thus be seen as having considerable significance for whether or not a young person begins and continues to commit criminal offences (Sarnecki 1986).

Sutherland also wrote of 'definitions favourable to the violation of law'. If an individual's perception of the law as something that can be broken is stronger than the same individual's perception of the law as something to be obeyed then, according to Sutherland, this will result in the commission of crime (Sutherland 1947). Sutherland never goes any deeper into the question of how the learning of criminal/conformist behaviour takes place. For this reason Burgess and Akers (1966) integrated Sutherland's theory from 1947 with 'modern learning theory' (Akers 1998). Akers describes in some detail the processes which lead to the reinforcement of pro- and anti-social behaviours at the individual level. In the matter of the conditions in which the learning of antisocial behaviour takes place, Akers too sees different types of primary groups, and not least groups consisting of peers, as the central factors.

The reinforcement can be nonsocial (as in the direct physiological effects of drugs or in unconditioned reinforcers such as food). But the theory posits that the principal behavioural effects come from interaction in or under the influence of those groups with which one is in differential association and which control sources and patterns of reinforcement, provide normative definitions, and expose one to behavioural models. The most important of these are primary groups such as peer and friendship groups and the family, but they also include work, school, church, and other membership and reference groups. (Akers 1998: 63)

The approach to the learning of criminal/conformist behaviour formulated in the above quotation is fully compatible with the modern network perspective. It should nonetheless be emphasised that the model is

applicable not only to delinquency but to all forms of behaviour, of which criminality is but one. Methods used to study interactions between individuals and their networks are thus on the whole the same, regardless of whether it is a question of examining how membership in a 'professional' network affects doctors' choices in relation to new medicines (Coleman, Katz and Menzel 1957) or how young people choose to commit certain types of offence or to use certain types of drug.

Finally, it is worth mentioning that the term 'differential association' is today used even outside the field of criminology. Morris (1994: 27) for example talks of differential associations in connection with his description of the epidemiological spread of contagious disease. He makes the point that the methods of network analysis are particularly suited to this area of study.

### 1.3.3 Subcultures

Discussions touching on the significance of social networks in the aetiology of criminal behaviour highlight the issues of deviant subcultures and delinquent gangs. Criminological theory contains two different models for explaining the formation of deviant subcultures and gangs. The first explains these phenomena as the result of social disorganisation, the other in terms of strain.

Shaw and McKay (1942) saw the causes of crime in the social disorganisation prevalent in those parts of metropolitan areas populated by the poor, who often came from ethnic minorities. In these neighbourhoods, the predominant societal culture exerts only a weak influence and inhabitants choose a deviant rather than a conventional lifestyle relatively often. Such choices of lifestyle are often collective in nature. Young people, antagonistically disposed towards societal norms, and even their own parents, can thus find support for deviant lifestyles among their contemporaries. This sometimes leads to the formation of gangs. In turn, gangs evolve a delinquent tradition of their own which is then passed on to new recruits. Once a gang tradition has been established, it will often continue irrespective of any changes taking place in the neighbourhood. The tradition is thus passed on from one generation of juveniles to the next, or from one ethnic minority to another, as new groups come to predominate when the older inhabitants move away (Einstadter and Henry 1995: 133).

Shaw and McKay (1942) suggest that in such areas, a tradition of delinquent behaviour can evolve to become an established norm. Youngsters growing up in the area see a number of the older youths making a success of their delinquent lifestyle and use these as role models for their own

behaviour. Alternative models for success are unlikely to be available in such areas.

Shaw and McKay's view of how such deviant cultures are passed on was influenced by an earlier version of Sutherland's (1939) theory of differential association (see above). They write:

Of particular importance is the child's intimate association with predatory gangs or other forms of delinquent and criminal organisation. Through his contacts with these groups and by virtue of his participation in their activities he learns the techniques of stealing, becomes involved in binding relationships with his companions in delinquency, and acquires the attitudes appropriate to his position as a member of such groups. (Shaw and McKay 1942: 436)

This quotation contains a description of deviant subculture and delinquent gang formation of a kind that is relatively rare in the criminological literature.<sup>11</sup> Youths living in the same part of town form contacts with one another and find in this new group a means of sheltering from the disorganised values of their surroundings. The interactions within such networks involve the transference of norms, values and forms of behaviour. It is not unusual for these interactions to involve co-offending both in terms of individual acts and as a lifestyle for the members in the network. Coleman *et al.* (1957) maintain that networks are of considerable importance for the forms taken by behaviour where there is uncertainty as to the norms which apply. This could be relevant for juveniles living in 'zones of transition' as Shaw and McKay describe the poor, immigrant neighbourhoods where this process of neighbourhood impoverishment coincides with the maintenance of thriving subcultures.

The other model explaining the emergence of deviant subcultures is rooted in Merton's (1938) strain theory. This perspective sees subcultures as emerging as a result of the strain experienced by young members of the underclass<sup>12</sup> when they realise that their chances of achieving the kind of goals recognised by mainstream society are very limited. Cohen (1955), for example, suggests that as a result of strain, youths from the underclass reject the middle-class values that are predominant in society and acquire instead a set of oppositional and delinquent norms and values. Of the four ways of dealing with strain described by Merton,<sup>13</sup> Cohen appears to be most interested in the last – rebellion. For him, delinquent subcultures arise in reaction to the strain experienced by underclass youth. Such youths react to their 'status frustration' by turning the middle-class values on their head and becoming violent and destructive.

Miller (1958), too, felt that the culture of the underclass was for the most part divorced from the predominant middle-class culture. For Miller, the underclass culture is characterised by delinquency, violence, the glorification

of physical strength and masculinity, bravery, risk-taking, excitement and sensation-seeking, as well as freedom from authority and so forth. According to Miller, the reason youths from the underclass commit criminal offences is to be found in their socialisation in an underclass value system, in terms of which such acts do not involve a deviation from norms. For Miller, this underclass culture is not limited to youth, but rather includes the whole of the underclass, even if it is among the young that it manifests itself most.

Cloward and Ohlin (1960) write of the 'conflict gang'. Unlike Cohen's gangs, however, the young people described by Cloward and Ohlin seem to be much more aware of the causes underlying their situation and are therefore much more purposeful in their struggles with the unjust societal structure which denies them the developmental opportunities they need. For Cloward and Ohlin, underclass youths react in a spirit of anger toward a society which so limits their chances of achieving established goals.

Agnew (1985), who revised Merton's strain theory, ascribes anger and frustration a central role in the causation of crime: 'Rather than being rationally directed, however, this anger is more the outbursts of youth frustrated by the constraints of a wide range of painful constraining situations from which they may wish to escape but are only able to *with peer support* through delinquent behaviour' (quoted in Einstadter and Henry 1995: 165, emphasis added).

In my opinion, this 'peer support' is the central factor in the context of transmission of delinquency. Strain may well have different effects depending on whether an individual is tied into a network comprising others in the same situation, has contacts of a different kind, or is socially isolated. It is likely that the 'rebellious' response described by Merton is much more probable if the anger resulting from social injustices can find a collective expression, with the individual finding support in a group of like-minded, contemporary peers. A more isolated individual might perhaps tend to choose other strategies to cope with strain, such as 'retreatism' for example. In addition, the individual's way of coping with strain may also be affected by the behavioural models that are available in his or her network. This last point is one which can be examined, at least in part, within the framework of the current project.

### 1.3.4 Neutralisation

The conception of a separate underclass culture has come in for a fair amount of criticism.<sup>14</sup> Sykes and Matza (1957) produced evidence suggesting that delinquent youths in fact embrace established, conventional norms

to a considerable degree. They write that 'there is a good deal of evidence suggesting that many delinquents *do* experience a sense of guilt or shame . . .' (p. 665).

Sykes and Matza's argument is based on Sutherland's perspective, seeing delinquency as a behaviour that is learned in the course of a process of interaction. They write: 'Unfortunately, the specific content of what is learned – as opposed to the process by which it is learned – has received relatively little attention in either theory or research. Perhaps the single strongest school of thought on the nature of this content has centred on the idea of a delinquent subculture' (Sykes and Matza 1957: 664).

For Sykes and Matza, techniques which neutralise the effect of the existing system of norms are an important aspect of what youths learn in the course of their associations with models for deviant behaviour (or as one might put it today, in the context of their social networks). Thus young people learn ways in which delinquent acts and other breaches of the prevailing norm system, a norm system which they otherwise embrace, can be justified. Here too Sykes and Matza align themselves with Sutherland by seeing these neutralisation processes as central to what Sutherland calls 'definitions favourable to violation of law'. According to Sykes and Matza, then, an individual becomes deviant by learning techniques of neutralisation and not by learning attitudes, values and norms which contradict those of the prevailing mainstream culture.

Matza further develops his view of neutralisation as a mechanism central to the development of delinquency in his *Delinquency and Drift* (1964). Here he introduces the concept of 'drift', which we can see as a half-way house between the positivist, determinist view of delinquency as a result of pre-existing conditions and the classical 'rational choice' view of crime as the result of an individual's choosing between alternative ways of acting in a given situation. According to Matza, the young delinquent drifting towards crime is neither completely free to make his own choices nor entirely constrained by circumstances: 'Drift stands midway between freedom and control. Its basis is an area of the social structure in which control has been loosened, coupled with the abortiveness of adolescent endeavor to organize an autonomous subculture, and thus an independent source of control, around illegal action' (Matza 1964: 28).

The intimated dissolution of the bonds of social control tying the individual to mainstream society may well take place within groups of peers. Matza refers in this regard to a collective misunderstanding, which involves the mistaken belief that one's friends are accepting of a great deal more delinquency, substance abuse and so forth than they actually are. Matza's point is

that it is youths with weak bonds to others who run the highest risk of being affected by this misunderstanding. He adds, however, that the desire for acceptance and status within the group (network) will limit the degree of honesty with which even those with a high degree of group involvement can discuss the acceptability or unacceptability of different types of behaviour (p. 56).

The desire to be accepted within the group usually weakens as the juveniles become older, but there are those, primarily men, who according to Matza are unable to establish a position for themselves in the labour market and who fail to establish relations with women of the same age. These individuals thus remain dependent on their contacts in the gang. These young adults maintain contact with the group which from Matza's point of view is 'Obviously . . . quite functional in the transmission of the subculture' (p. 56). At the same time, however, older youths cannot continue to associate with considerably younger juveniles indefinitely. This is seen by the young adults as humiliating in the context of their efforts to attain the status of 'grown men'.

### 1.3.5 Gangs

Descriptions of a specific type of criminal network, namely the gang, are widespread in the criminological literature. Thanks to comprehensive gang research, we know a considerable amount about the influence that active members of delinquent gangs have on one another. It should nonetheless be emphasised that gangs are not the only, and are not even the most common, form of crime-generative juvenile peer group (Klein and Crawford 1967; Morash 1983). Even if the definition of what constitutes a gang varies somewhat in the literature, it is quite obvious that the majority of group-related offences committed even in the metropolitan areas of North America are not carried out by gangs (Klein 1995, Short 1998b). In this context it might be useful to present the distinction made by Knox (1991) between gang-related crime and other group-related crime. The difference according to Knox is that the delinquency of gang members (often) takes place as a result of gang membership and is accepted and encouraged by the gang. This is not the case with offences committed by members in other forms of delinquent group (Knox 1991: 6). It should be noted, of course, that gang members also commit offences that are unrelated to their gang membership.

As I have already indicated, in spite (or perhaps because) of the comprehensive gang literature, academics active in this area have been unable to agree on a common definition of the gang concept (Thrasher 1927; Empey

and Stafford 1991; Huff 1991, 1996; Klein 1995; Decker and Van Winkle 1996; Short 1996; Klein *et al.* 2001).

In a comment on Klein's (1995: 102–3) statement that variations in police definitions of gangs are confusing, Short writes:

Unfortunately, definitions used by researchers are only slightly less so. It is no wonder that many who study youth collectivities do not use the term, choosing instead to study 'co-offending' (Reiss, 1986; Reiss and Farrington, 1991), 'bands of teenagers congregating on street corners' (Skogan, 1990), 'cliques' (Sullivan, 1989), 'unsupervised peer groups' (Sampson and Groves, 1989), 'peer groups' (McLeod, 1987), 'reference groups' (Sherif and Sherif, 1964), 'networks' of juveniles who violate the law (Sarnecki, 1986), or simply 'delinquent groups' (Warr, 1996). (Short 1998b: 15)

Some writers even suggest that a common definition will never be agreed and that its absence may well be productive for gang research. Horowitz (1991) writes: 'Agreement will likely never be achieved, and definitions often obscure problematic areas and may not encourage the development of new questions . . .' (p. 38).

Short and Horowitz thus contend both that there is a great deal of confusion surrounding the gang concept and that ironing out this confusion might in fact prove counter-productive. A review of the literature on American gangs nonetheless provides us with a number of elements which seem to crop up in the vast majority of definitions of the gang. Curry and Decker (1998) suggest that the following elements can be found in most of such definitions:

Gangs are groups of individuals.

Gangs have some form of symbol indicating gang membership (special items of clothing, tattoos, hand signals etc).

A specific form of communication<sup>15</sup> (which may be verbal or non-verbal – such as special words, hand signals or graffiti).

Durability (at least a year).

Territory (turf) which the gang defends. (This may be the area where the gang started its life, where most of the members live, or where members sell drugs, for example.)

Delinquency. (Gangs are deeply involved in criminal activity and see this as a feature of membership in the gang: pp. 2–6.)

Curry and Decker point out that it is sometimes easier to define who is a member of a gang than to define what a gang consists in: 'The most powerful measure of gang membership is self nomination. By this we mean that simply asking individuals whether or not they belong to a gang –

“claiming” in gang talk – is the best means of identifying who is a gang member’ (p. 6).

Despite the lack of a generally accepted definition of the gang concept, a review of the modern American literature in this area (Hagedorn and Macon 1988; Sanchez-Jankowski 1991; Huff 1991, 1996; Knox 1991; Moore 1991; Padilla 1992; Klein 1995; Decker and Van Winkle 1996) gives the impression that the majority of gang researchers would agree on most of the points included by Curry and Decker in the description cited above of characteristics typical of gangs. The differences in the descriptions of gangs that can nonetheless be found in the work of these authors have mainly to do with the degree of organisation and the significance of drugs, primarily of drug sales, for the life of the gang. Certain of the gangs described in the literature (e.g. the ‘Diamonds’ studied by Padilla (1992), and the forty or so gangs from New York, Boston and Los Angeles studied by Sanchez-Janowski (1991), as well as some of the gangs in Huff’s anthology, such as the Chinese gangs described by Ko-Lin Chin (1991)) seem to be more well-organised than others and to assign different roles to members on a much more rigid basis. This is probably a consequence of such gangs being more strictly focused on a certain type of crime (most often involving the distribution of drugs, but other forms of crime such as protection rackets, for example, are also found) and this focus demands a more rigid form of organisation.<sup>16</sup>

Over the last few years it has been pointed out that gangs are in no way a uniform phenomenon. Klein is of the opinion that there is a clear difference between what he calls ‘street gangs’ and prison or drug gangs, for example. For Klein, the concept of the ‘juvenile, youth or delinquent gang’ that was previously in common usage is no longer relevant, since gangs increasingly include individuals of twenty years of age or older (1995: 21). His *The American Street Gang. Its Nature, Prevalence and Control* excludes such delinquent groups as skinheads and motorcycle gangs from its analyses, a factor which Klein motivates in the following way: ‘Street gangs seem aimless; skinheads and bikers are focused, always planning. Street gangs’ members get into any and every kind of trouble. It’s cafeteria-style crime – a little of this, a touch of that, two attempts at something else’ (p. 22).

When Klein defines the characteristics which make a group classifiable as a street gang, he writes of:

young people, who may range in age from 10 to 30 or occasionally older, whose cohesion is fostered in large part by their acceptance of or even commitment to delinquent or criminal involvement. They are principally but not exclusively male, principally but not exclusively minority in ethnicity or race, normally but not necessarily territorial, and highly versatile in their criminal offences. These

offences are not predominantly violent, but they are disproportionately violent when compared with the activities of other youth groups or individual persons . . . (p.75)

Klein's characterisation of street gangs is strikingly similar to the descriptions of gangs to be found in Thrasher's classic work on this phenomenon, *The Gang* (1927).<sup>17</sup> Even then, Thrasher saw the relationship between the emergence of gangs and the conditions in which young people, not unusually from ethnic minorities, are forced to live in a metropolitan area. For Thrasher the boys look for membership in this kind of group in order to experience 'the thrill and zest of participation in common interest, more especially in corporate action, in hunting, capture, conflict, flight and escape. Conflict with other gangs and the world about them furnishes the occasion for many of their exciting group activities' (p. 37).

Thrasher suggests that gangs grow out of spontaneously formed groups of young people when the bonds linking the members of the group to one another become strengthened as a result of conflict. This process consists of three stages. During the first stage, the group's boundaries are diffuse and its leadership unclear. Such gangs often survive for only a short time. Some gangs continue to evolve to the next stage, however, where membership boundaries and the leadership structure become more defined. This tends to be the result when the group is jointly subjected to some kind of threat. If, during the period which follows, the group members do not make the transition to a normal adult life as part of conventional society, the bonds between them can become further strengthened and the group's activity and the whole of its existence become focused on delinquency.

As with many later 'gang researchers', Thrasher felt that even though gang members commit many different kinds of offence, violent crimes play a central role in the life of the gang. This violence, both that which is directed at members of other groups, and that which members of other groups direct at the gang, works as a unifying factor and increases solidarity within the group. For Thrasher, however, gangs have no homogeneous structure but instead contain subgroups of members.

During the 1960s a number of studies were carried out in connection with ongoing crime-prevention programmes aimed at juvenile gang members (Short and Strodbeck 1965; Spergel 1966; Klein 1971). In theoretical terms, these studies were on the whole underpinned by the subculture theories mentioned earlier in this chapter, that is, Cohen (1955), Cloward and Ohlin (1960) and Miller (1958). These studies give us the chance to better understand the group processes which take place in a gang and which lead

to the gang culture being passed on. They can also give us some insight into the processes which lead to the correlation between underclass culture and resultant delinquent behaviour. Short and Strodbeck, for example, focus on 'hypotheses relating to mechanisms by which norms and values associated with structural variation become translated into behaviours' (1965: 269).

These writers see the behaviour of criminally active gang members as a result of attempts to adapt to the conditions in which they live. For Short and Strodbeck, participation in a delinquent peer group provides a feeling of belonging that to some degree compensates for all the failures these individuals have experienced 'in every strata of society and at every age' (Short and Strodbeck 1965: 271). In turn, such failures result from the inability of the youngsters' parents, and of others in their social networks, to equip them with the social competence necessary to achieve any degree of success in conventional society. Seeking to compensate this shortfall by means of membership in a gang, however, often has devastating consequences. Membership in a group whose culture is predominantly that of the underclass and often also of ethnic minorities leads to a further worsening of social competence. In addition, membership in a gang where conflict with others is an important element (giving an individual status) means that these individuals are exposed to the risk of physical injury or even death as a result of violence.

In their study of gangs in Chicago, Short and Strodbeck find that relations within these gangs are often short-lived and unstable. They suggest that this is due to the unstable conditions in which the gang members live, their lives being characterised by unemployment or by brief periods of employment, a lack of stability in family life, and unstable housing conditions.

Vulnerable youths thus look to gangs to satisfy a number of needs such as a need for shelter, identity, excitement, a sense of belonging, and status. The trouble is that gangs seldom satisfy these needs. Instead of finding shelter, gang members become even more exposed and vulnerable; instead of excitement, they find themselves spending day after day on a street corner. Groups are often very loosely formed, so the need for a sense of belonging is left unsatisfied, and within the group the individual often finds his social status being threatened (Short 1990).

It is clear that the youths who look to become gang members want to be part of a cohesive group. The fomentation of conflicts with other gangs and the frequent resort to violence are means of increasing group solidarity. According to a number of researchers (e.g. Klein 1995) cohesiveness is important both for a gang's durability and for its criminal activity. As was

mentioned earlier, however, the level of cohesiveness shown by such delinquent groups seems to vary and remains a matter for debate.

Yablonsky (1962) lists a number of characteristics often ascribed to gangs by social workers and others. Among these are: an ascertainable number of members; the members are identifiable, that members have specified roles, that members agree on the rules of the gang, that there is clear leadership and so on. Yablonsky maintains that these characteristics are often missing from actively delinquent groups of young people. In his own work, he therefore chooses instead to speak of 'near groups'. If social workers (or detached workers) expect to find these characteristics in the gang, then this will contribute to increasing the gang's cohesiveness which may mean that such characteristics arise or are strengthened as a result of the workers' interest. Being seen by others as a unified group will have an effect on a group's cohesiveness. The perceptions of social workers, the police and the local press on such matters can easily become self-fulfilling prophecies (Klein 1995, cf. Merton 1968).

Klein (1995) states that the number of street gangs in the USA has increased dramatically over the last few decades. Gangs are no longer a purely metropolitan phenomenon. Klein sees the causes of this increase in the expansion of the urban underclass. He refers to Wilson (1987) who in his *The Truly Disadvantaged* argues that over the last few decades poor neighbourhoods in American cities have become further impoverished. This impoverishment is understood in part as a result of the reduction in the availability of unqualified industrial work, which provided the ghetto population's primary source of income. The simultaneous increase in service sector jobs has only partly eased the situation, since young men from the ghetto often lack the necessary qualifications (i.e. social competence) for such positions, which are often also extremely poorly paid.

In addition to the problem of unemployment, the poor metropolitan neighbourhoods have been further impoverished as a result of the way in which better-educated members of the minority groups that populate these areas (chiefly blacks and Latin-Americans) are now able to move away to middle-class neighbourhoods which were previously populated more or less exclusively by whites. As the middle class moves away, many institutions such as active churches, youth clubs, day-care centres etc., all of which are vital to the social life of the neighbourhood, also disappear. The school system also deteriorates (Wilson 1987).

Such a deterioration in the living conditions of people who reside in neighbourhoods that are increasingly ethnically segregated, correspondingly increases the pressure on family life, which in turn also suffers.
