

The Neuroscience of Language

The Neuroscience of Language offers a remarkably accessible introduction to language in the mind and brain. Following the chain of communication from speaker to listener, it covers all fundamental concepts from speech production to auditory processing, speech sounds, word meaning, and sentence processing. The key methods of cognitive neuroscience are covered, as well as clinical evidence from neuropsychological patients and multimodal aspects of language including visual speech, gesture, and sign language. More than eighty full-color figures are included to help communicate key concepts. The main text focuses on big-picture themes, while detailed studies and related anecdotes are presented in endnotes to provide interested students with many opportunities to dive deeper into specific topics. Throughout, language is placed within the larger context of the brain, illustrating the fascinating connections of language with other fields including cognitive science, linguistics, psychology, and speech and hearing science.

Jonathan E. Peelle is an associate professor in the Center for Cognitive and Brain Health at Northeastern University, with appointments in the Department of Communication Sciences and Disorders and the Department of Psychology. He has taught undergraduate and graduate courses on the neuroscience of language; speech, language, and hearing science; cognitive neuroscience; and functional brain imaging. He is a reviewing editor for *eLife* and *Neurobiology of Language*, and former reviewing editor for *NeuroImage* and *Language, Cognition and Neuroscience*. He has authored more than eighty papers on the neuroscience of language and is currently the chair of the Society for the Neurobiology of Language.

Cambridge Fundamentals of Neuroscience in Psychology

Developed in response to a growing need to make neuroscience accessible to students and other non-specialist readers, the *Cambridge Fundamentals of Neuroscience in Psychology* series provides brief introductions to key areas of neuroscience research across major domains of psychology. Written by experts in cognitive, social, affective, developmental, clinical, and applied neuroscience, these books will serve as ideal primers for students and other readers seeking an entry point to the challenging world of neuroscience.

Books in the Series

The Neuroscience of Expertise by Merim Bilalić
Cognitive Neuroscience of Memory by Scott D. Slotnick
The Neuroscience of Intelligence by Richard J. Haier
The Neuroscience of Adolescence by Adriana Galván
The Neuroscience of Suicidal Behavior by Kees van Heeringen
The Neuroscience of Creativity by Anna Abraham
Cognitive and Social Neuroscience of Aging by Angela Gutches
The Neuroscience of Sleep and Dreams by Patrick McNamara
The Neuroscience of Addiction by Francesca Mapua Filbey
Introduction to Human Neuroimaging by Hans Op de Beeck and Chie Nakatani
The Neuroscience of Sleep and Dreams, 2nd edition by Patrick McNamara
The Neuroscience of Intelligence, 2nd edition by Richard J. Haier
The Cognitive Neuroscience of Bilingualism by John W. Schwieter and Julia Festman
Fundamentals of Developmental Cognitive Neuroscience by Heather Bortfeld and Silvia A. Bunge
Cognitive and Social Neuroscience of Aging, 2nd edition by Angela Gutches
Cognitive Neuroscience of Memory, 2nd edition by Scott D. Slotnick
The Neuroscience of Language by Jonathan E. Peelle
Neuroscience of Attention by Joseph B. Hopfinger
Introduction to Human Neuroimaging, 2nd edition by Hans Op de Beeck and Chie Nakatani

Figures

1.1	Schematic of the “speech chain”.	<i>page 2</i>
1.2	Categorical perception of speech illustrated by a continuum between “pa” and “ba”.	5
2.1	Schematic of a neuron.	17
2.2	Human neuroscience methods reflect tradeoffs in spatial and temporal resolution.	19
2.3	Three views of a structural MRI image of the brain.	21
2.4	Example images from DTI.	22
2.5	Example EEG cap and data.	25
2.6	MEG scanner.	27
2.7	Example fMRI data.	28
2.8	Example fNIRS cap and data.	32
2.9	Illustrative comparison of how to compare brain activity in two conditions.	34
2.10	Distribution of brain damage in three subtypes of frontotemporal dementia.	36
3.1	Example of a classic phrenology diagram.	46
3.2	Portrait of Pierre Paul Broca.	47
3.3	Brains of Broca’s famous patients Leborgne and Lelong.	49
3.4	Reproduction of the Wernicke-Lichtheim model of language.	50
3.5	Schematic illustration of how unobservable cognitive processes affect the relationship between experimental manipulations and observable data.	53
3.6	Gyri and sulci form “mountains” and “valleys” in the cortex.	54
3.7	Common brain directions and modifiers.	55
3.8	Lateral views of the brain highlighting major sulci and lobes.	56
3.9	Major divisions of the frontal and temporal lobes.	57
3.10	Midsagittal view of the right hemisphere highlighting lobes and major landmarks.	57
3.11	Cytoarchitectonic map of Brodmann (1909).	58
3.12	Axial, coronal, and sagittal planes of the brain.	60
3.13	Key white matter tracts reconstructed from DTI.	62
3.14	Schematic of a dual-stream model for speech.	63
3.15	Anatomical connectivity between the frontal and temporal lobe in monkeys.	64
4.1	Stages of speech production.	71

List of Figures

ix

4.2	Example image from real-time MRI showing anatomy of speech production.	72
4.3	Brain regions associated with motor execution and planning.	73
4.4	Macroanatomical subdivisions of the left inferior frontal gyrus.	75
5.1	Hair cells along the Organ of Corti in the guinea pig cochlea.	92
5.2	Example audiogram.	94
5.3	Characteristic audiograms associated with hearing difficulty.	95
5.4	Subcortical auditory processing pathways.	96
5.5	Typical stimuli and recorded responses for the ABR and FFR.	97
5.6	Anatomy of the superior temporal plane.	99
5.7	Auditory cortex subdivisions in nonhuman primates.	100
5.8	Schematic of a cochlear implant.	106
6.1	Sound pressure and spectrogram for a pure tone and syllable.	117
6.2	Bilateral posterior superior temporal sulcus.	119
6.3	Illustration of noise vocoding.	121
6.4	Illustration of temporal response function analysis.	125
6.5	Experimental results from Blank and Davis (2016) comparing sharpened signal versus prediction error models for neural responses to speech.	127
6.6	Illustration of how voice onset time differentiates the nonwords “pife” and “bife”.	129
6.7	Schematic illustrating the experimental paradigm of Dilley and Pitt (2010).	131
6.8	Portrait of Dr. Juhn Wada.	134
7.1	Behavioral results from Warrington and Shallice (1984) illustrating category-specific semantic deficits.	146
7.2	Results from Bonner and Grossman (2012) showing gray matter atrophy and lexical decision performance for people with the logopenic variant of primary progressive aphasia.	150
7.3	Animals drawn hastily a professor to illustrate characteristic features.	154
7.4	Brain damage in the semantic variant of primary progressive aphasia is most severe in the left temporal pole.	155
7.5	The angular gyrus.	155
7.6	Differences in brain activity between abstract and concrete words.	158
7.7	A hub-and-spoke framework for semantic memory	160
7.8	Cartoon of the Dynamic Multilevel Reactivation Framework of semantic memory.	160
7.9	Illustration of semantic spaces.	161
7.10	Simplified example of lexical co-occurrence in text.	162
8.1	The lateral anterior temporal lobe.	172

x	List of Figures
8.2	Relationship between cortical thickness of the angular gyrus and combinatorial judgments (Price, Bonner and colleagues, 2015). 173
8.3	Schematic of the “red boat” task from Bemis and Pyykkänen (2011). 174
8.4	Brain regions associated with intelligible sentence processing. 176
8.5	Brain regions associated with semantic disambiguation during sentence processing. 178
8.6	Meaning priming declines over time (Rodd and colleagues, 2016). 180
8.7	Brain regions associated with understanding syntactically complex sentences. 182
8.8	Results from a word monitoring task in people with FTD (Grossman and colleagues, 2005). 183
8.9	Experimental design and results from Ding and colleagues (2016) looking at neural power at frequencies corresponding to words, phrases, and sentences. 185
8.10	Schematic showing experimental design of Riecke and colleagues (2018) in which tACS was used to improve the understanding of speech in noise. 186
8.11	The phase of ongoing oscillations can affect how incoming stimuli are processed. 188
9.1	The left posterior temporal sulcus. 198
9.2	Susceptibility to the McGurk illusion does not correlate with visual benefit when listening to sentences in noise (Van Engen and colleagues, 2017). 200
9.3	Areas responding more to voice stimuli than control conditions. 202
9.4	Brain regions associated with integrating meaning from gesture. 207
10.1	Static model of language processing in the brain informed by modern cognitive neuroscience. 217
10.2	Some of the many factors affecting demands listeners face during spoken communication. 218
10.3	Degradations, deviations, and distractions can challenge speech perception. 219
10.4	Relationship between acoustic challenge, speech intelligibility, and listening effort 221
10.5	The cingulo-opercular network. 225
10.6	DLPFC activity in listeners with cochlear implants during speech understanding. 226
10.7	Regions of the frontal cortex associated with conversation planning. 227
10.8	Functional subdivisions of the cerebellum (from Nettekoven and colleagues, 2024). 228
10.9	The dynamic processes listeners need to engage during speech understanding depend on task demands and listener abilities. 229

Preface

As a researcher, one of the things I've appreciated most about language research is how many other areas of science it comes into contact with: memory, decision-making, acoustics, audiology, linguistics . . . the list goes on. One of the joys of teaching students about the neuroscience of language has been to make connections with other areas of their lives, and I've enjoyed trying to convey this enthusiasm and some of the many fascinating facets of human language throughout this textbook.

The chapters are written so that they can be read in any order, although the first three chapters provide background in terminology and methods that is assumed in subsequent chapters. When I teach this class, I mostly go in order (with some skipping around at the end).

One difference you may notice between this textbook and some others: I have broken with textbook tradition and included a great deal in endnotes. I had several inspirations for doing so. First, for people new to the field – that is, the intended audience of the book – filling the main text with parenthetical citations is not particularly meaningful, and I worried it would actually distract them from the main points. However, having done my best to simplify the text, I wanted to be sure both to give credit where it's due – the endnotes include primary references to support claims made in the text – and to offer interested readers not only more details (and interesting tangents) but also some commentary based on my own perspective. My goal is that the main text is readable and understandable without ever reading an endnote, but that endnotes will be useful and interesting for readers who want a bit more. One teaching strategy that works well is to review specific studies during lectures, or assign research articles as additional class reading, to highlight specific aspects of research. In addition to sources noted in endnotes, each chapter includes a handful of suggestions “for further reading” that can be used for these activities.

Another way in which I have broken with textbook tradition is that I have included a number of figures that I've created myself, including figures summarizing brain imaging results. (It is relevant to note at this point that I am not an artist.) I've modeled these figures from what I would include in a lecture – for example, what I might draw on a blackboard while explaining a concept.¹ As with the written text, these figures are meant to convey main ideas in a consistent visual format, and should not be taken as a substitute for referring to primary research. I envision a useful strategy is to supplement these

simplified figures with specific examples of research results in class. The figures I created for this book are available from <https://osf.io/geqb6/>.

The boxes included throughout are intended to highlight specific concepts that complement the main text. In many cases, they introduce new and complementary topics, and contain endnotes with additional information. One possibility – which I have done in my own teaching – is to assign small groups to dig into one of these “tangential” areas and read one or more of the references appearing in a box or endnote, giving them an opportunity to dive a little bit deeper into an area, supported by the background of suggested readings and context provided by the textbook.

Some of the boxes also include stories of real people whose life experience relates to the neuroscience of language. To those who allowed me to share their stories: thank you! Your contributions have helped make this book richer and more personal. To the readers, I would like to point out that most of the people I interviewed are people I have had contact with in real life, and I suspect many of *you* also know people with interesting stories about the neuroscience of language. As you read this book it may be worth thinking about whether there is someone in your own circle whose experience you can learn from.

To all my colleagues in the field: thank you for all of your wonderful contributions to our understanding of the neuroscience of language, and please forgive my oversimplifications (and, no doubt, mistakes). I have aimed to present enough information to give readers a broad understanding of some of the biggest issues in the field and prepare (if they so choose) for further and deeper study. I have very specifically tried *not* to present every experimental finding or theoretical viewpoint, even very good ones, to prevent information overload. I have also avoided certain paradigms and analysis approaches that I judged too complicated for an introductory text, no matter how compelling. I am very aware that many laudable studies are not included here and I’m sorry if yours is among them.

Note

1. During my PhD, I had the good fortune to be taught foundations of neuroscience by Eve Marder, who during her lectures notoriously avoided PowerPoint slides in favor of colored chalk (described eloquently in Marder, 2000). And now you have a concrete example of one of the ways I use endnotes in this book.

Acknowledgments

This book was not written in a vacuum and I am deeply grateful to all who supported and encouraged me during its writing.

I am grateful to Scott Slotnick, who first approached me about this project, and Stephen Acerra, Jackie Grant, and the rest of the team at Cambridge University Press, who not only brought the book to completion but made it better along the way. Their encouragement, feedback, and patience were instrumental throughout the process.

I am also incredibly grateful to my colleagues in the field of cognitive neuroscience, particularly the neuroscience of language, for their thoughtful research and interactions. I have benefited incalculably from prior review papers, chapters, talks, and personal interactions over the last 20-plus years. I am particularly indebted to my primary mentors – Art Wingfield, Murray Grossman, and Matt Davis – who taught me about science, speech, and language, and even more importantly, about being a kind and thoughtful human being.

I have included experiences of actual people to help illustrate everyday experiences related to language processing. The stories and people are all real, although some details may have been changed to provide anonymity. I am deeply grateful to everyone who took the time to speak with me and let me share their story.

I am also grateful to authors of academic software that has helped me to both learn neuroimaging analysis and provide some of the figures in this book, including (but not limited to) Chris Rorden for his wonderful MRICroGL (and its predecessors, MRICro and MRICron), the SPM development team at the Wellcome Centre for Human Neuroimaging, and the FSL development team at Oxford University. Developing this software, publishing methodological articles on the underlying algorithms, sharing the code, and organizing workshops and training opportunities has benefited countless scientists through the years.

The book was improved at all stages by many people who provided helpful feedback, especially Kristin Van Engen, Kristen Allison, Drew McLaughlin, Kate McClannahan, Erin Meier, Emily Myers, and Jamie Reilly. I am indebted to their thoughtfulness and useful suggestions. I am also grateful to many lab members, students, friends, and family members who took the time to read and proofread sections of the book.

Finally, I am grateful to Abram Van Engen for convincing me that writing a book was a good idea, and to my family for their constant love and support.
