

Theory and Computation of Hydrodynamic Stability

The study of hydrodynamic stability is fundamental to many subjects, ranging from geophysics and meteorology through to engineering design. This treatise covers both classical and modern aspects of the subject, systematically developing it from the simplest physical problems, then progressing to the most complex, considering linear and nonlinear situations, and analyzing temporal and spatial stability. The authors examine each problem both analytically and numerically. Many relevant fluid flows are treated, including those where the fluid may be compressible, or those from geophysics, or those that require salient geometries for description. Details of initial-value problems are explored equally with those of stability.

The text includes copious illustrations and an extensive bibliography, making it suitable for courses on hydrodynamic stability or as an authoritative reference for researchers. In this second edition the opportunity has been taken to update the text and, most importantly, provide solutions to the numerous extended exercises.

W. O. CRIMINALE is Professor Emeritus in the Department of Applied Mathematics at the University of Washington. His research focuses on the areas of initial-value problems in shear flows, large-scale oscillations in turbulent flows, mixing and nonlinear mechanics. Professor Criminale is the recipient of many honors, which include: the Alexander von Humboldt Senior Research Award; Fellow, American Physical Society; Guest Scientist, Stanford–Ames Turbulence Research Center; the Faculty Research Award, Battelle Pacific Northwest Laboratories; and Royal Society Fellow in the United Kingdom.

T. L. JACKSON is a research professor in the Department of Mechanical and Aerospace Engineering at the University of Florida, Gainesville. He is currently a fellow of the American Physical Society (APS), a fellow of the American Society of Mechanical Engineers (ASME), an associate fellow of the American Institute of Aeronautics and Astronautics (AIAA) and a member of the Combustion Institute. He was previously an associate editor for the *AIAA Journal*, and he currently serves on the editorial advisory board for the *AIAA Journal of Propulsion and Power*. His expertise is in the area of basic fluid mechanics, combustion, stability, solid propellant combustion, energetic material modeling and the large-scale simulation thereof.

R. D. JOSLIN is a permanent program director in the Engineering Directorate at the US National Science Foundation in Alexandria, Virginia. He manages the Fluid Dynamics Program and other cross-Foundation programs. Dr. Joslin was previously a program manager at the Office of Naval Research, where he managed the Turbulence, Stratified Wakes, Submarine Maneuvering, Ocean Energy, Multi-Platform Interactions and Supercavitation Programs. He is a member of the APS, ASME and is an associate fellow in the AIAA. His areas of expertise include fundamental fluid mechanics, turbulence and transition, stability theory, DNS/LES/CFD, supercavitation and renewable energy.

Established in 1952, the *Cambridge Monographs on Mechanics* series has maintained a reputation for the publication of outstanding monographs, a number of which have been re-issued in paperback. The series covers such areas as wave propagation, fluid dynamics, theoretical geophysics, combustion, and the mechanics of solids. Authors are encouraged to write for a wide audience, and to balance mathematical analysis with physical interpretation and experimental data, where appropriate. Whilst the research literature is expected to be a major source for the content of the book, authors should aim to synthesize new results rather than just survey them.

A complete list of books in the series can be found at

Contents

	<i>Preface to the Second Edition</i>	page ix
	<i>Preface</i>	xi
1	Introduction and Problem Formulation	1
	1.1 History, Background and Rationale	1
	1.2 Initial-Value Concepts and Stability Bases	11
	1.3 Classical Treatment: Modal Expansions	14
	1.4 Transient Dynamics	18
	1.5 Asymptotic Behavior	20
	1.6 Role of Viscosity	21
	1.7 Geometries of Relevance	23
	1.8 Spatial Stability Bases	23
2	Temporal Stability of Inviscid Incompressible Flows	26
	2.1 General Equations	26
	2.2 Kelvin–Helmholtz Theory	41
	2.3 Piecewise Linear Profile	44
	2.4 Inviscid Temporal Theory	50
	2.5 Critical Layer Concept	57
	2.6 Continuous Profiles	61
	2.7 Exercises	69
3	Temporal Stability of Viscous Incompressible Flows	76
	3.1 Introduction	76
	3.2 Channel Flows	77
	3.3 Blasius Boundary Layer	83
	3.4 Falkner–Skan Flow Family	86
	3.5 Unbounded Flows	88
	3.6 Discrete and Continuous Spectra	90
	3.7 Exercises	94

4	Spatial Stability of Incompressible Flows	98
4.1	Introduction	98
4.2	Gaster's Transformation	99
4.3	Incompressible Inviscid Flow	101
4.4	Absolute and Convective Instabilities	112
4.5	Incompressible Viscous Flow	116
4.6	Discrete and Continuous Spectra	120
4.7	Exercises	126
5	Stability of Compressible Flows	128
5.1	Introduction	128
5.2	Compressible Mixing Layer	129
5.3	Compressible Boundary Layer	151
5.4	Exercises	165
6	Centrifugal Stability	168
6.1	Coordinate Systems	168
6.2	Taylor Problem	170
6.3	Görtler Vortices	177
6.4	Pipe Flow	180
6.5	Rotating Disk	182
6.6	Trailing Vortex	185
6.7	Round Jet	187
6.8	Exercises	190
7	Geophysical Flow	191
7.1	General Properties	191
7.2	Stratified Flow	192
7.3	Effects of Rotation	208
7.4	Baroclinic Flow	213
7.5	The Ekman Layer	216
7.6	Exercises	222
8	Transient Dynamics	225
8.1	The Initial-Value Problem	225
8.2	Laplace Transforms	229
8.3	Moving Coordinates and Exact Solutions	232
8.4	Multiple Scale, Multiple Time Analysis	240
8.5	Numerical Solution of Governing Partial Differential Equations	244
8.6	Optimizing Initial Conditions	248
8.7	Exercises	257

<i>Contents</i>		vii
9	Nonlinear Stability	259
9.1	Energy Equation	259
9.2	Weakly Nonlinear Theory	261
9.3	Secondary Instability Theory	263
9.4	Resonant Wave Interactions	272
9.5	PSE Theory	278
9.6	Exercises	285
10	Transition and Receptivity	287
10.1	Introduction	287
10.2	Influence of Free Stream Turbulence and Receptivity	288
10.3	Tollmien–Schlichting Breakdown	291
10.4	Oblique Wave Breakdown	292
10.5	Crossflow Vortex Breakdown	294
10.6	Dean–Taylor–Görtler Vortex Breakdown	298
10.7	Transition Prediction	301

	<i>Subject Index</i>	549

Preface to the Second Edition

This second edition started soon after the first printing because it was recognized that this specialty field involves significant mathematics and the exercises at the end of each chapter may prove challenging to many. Therefore, it was determined that providing solutions to the exercises may be more useful to the learning process, and a number of solutions to the exercise problems are provided in Appendix C. We have also taken the opportunity to move the discussion of all of the numerical algorithms to one place, namely Appendix B. Also, many thanks to M. R. Malik and H. C. Kuhlmann for the published reviews of the first edition. Although the authors caught most of the issues presented in the reviews in the preprint process, the final printed version failed to address some typos and some poor quality images. It is our hope that this second edition will be more useful to the readers, especially with the addition of solutions to the exercises.

Preface

The subject of hydrodynamic stability, or stability of fluid flow, is one that is most important in the fields of aerodynamics, hydromechanics, combustion, oceanography, atmospheric sciences, astrophysics and biology. Laminar or organized flow is the exception rather than the rule to fluid motion. As a result, exactly what may be the reasons or causes for the breakdown of laminar flow has been a central issue in fluid mechanics for well over a hundred years. And, even with progress, it remains a salient question, for there is yet to be a definitive means for prediction. The needs for such understanding are sought in a wide and diverse list of fluid motions because the stability or instability mechanisms determine, to a great extent, the performance of a system. For example, the underprediction of the laminar to turbulent transitional region on aircraft – which is due to hydrodynamic instabilities – would lead to an underestimation of a vehicle's propulsion system and ultimately result in an infeasible engineering design. There are numerous such examples.

The seeds for the writing of this book were sown when one of us (WOC) was contacted by two friends, Philip Drazin and David Crighton, with the suggestion that it was perhaps time for a new treatise devoted to the subject of stability of fluid motion. A subsequent review was taken by asking many colleagues as to their assessment of this thought and, if this was positive, what should a new writing of this subject entail? The response was enthusiastic and revealed three major requirements: (i) a complete updating of all aspects of the field; (ii) the presentation should provide both analytical and numerical means for solution of any problem posed; (iii) the scope of the treatment should cover the full range of the dynamics, ranging from the transient to asymptotic behavior as well as linear and nonlinear formulations. Then, since the computer is now a major tool, a final need suggested that direct numerical simulation (DNS) must be included as well.

This challenge was accepted and with intensive collaboration, we have at-

tempted to meet these goals. All prototype flows are considered whether confined (Chapter 3), semi-confined (Chapter 3), in the absence of boundaries (Chapter 2) and both parallel, almost parallel or flows with curved streamlines (Chapter 6). In addition, the topics of spatial versus temporal stability (Chapter 4), compressible (Chapter 5) as well as incompressible fluids geophysical flows (Chapter 7), transition and receptivity (Chapter 10) and optimization and control of flows (Chapter 12) are given full attention. Also, specific initial-value problems (Chapter 8) would be examined as well as the question of stability. In every case, the basics are developed with the physics and the mathematical needs (Chapters 1, 2) with emphasis on numerical methods for solution. To this end, in formulating the organization of the book, it was decided that it would be beneficial if, at the end of each chapter that dealt with a specific topic, in addition to exercises for illustration, an appendix, when appropriate, would be attached that provided a numerical basis for that particular area of need. The reader would then be able to develop their own code. Nonlinear stability (Chapter 9) and direct numerical simulation, i.e., DNS (Chapter 11) are supplemented with a cursory review of what is known from experiments (Chapter 13).

The book can easily be used as a text for either an upper-level undergraduate or graduate course for this subject. For those who are already knowledgeable, we hope that the book will be a welcome and useful reference.

There are many friends who have helped us with the formulation and writing. Indeed, all have given us both criticism and advice when needed. Particular recognition should be given to Richard DiPrima, who was the mentor for one of us (TLJ) and was a person who provided more than a rationale to be engaged in the field of hydrodynamic stability with his teaching, expertise and major contributions to the subject. In a similar manner, Robert Betchov provided the initial impetus for another (WOC). More recently, M. Gaster, C. E. Grosch, F. Hu, D. G. Lasseigne, L. Massa and P. J. Schmid have made their time available so that our writing would benefit and the contents be made to fit our goal. To each, we extend our sincere thanks. And, to the late Robert Betchov, Dick DiPrima, David Crighton and Philip Drazin, a firm note of gratitude. The passing of our colleagues is a loss. Finally, we have had assistance from some who have helped with technical needs. In particular, Frances Chen, Michael Campbell and Peter Blossey should be cited.
